RELATION OF DRUG THERAPY TO NEUTROPENIC STATES

CHAIRMAN'S ADDRESS

ROY R. KRACKE, M.D.

EMORY UNIVERSITY, GA.

In 1931 the first evidence was presented that the disease agranulocytosis was caused by the administration of certain drugs.¹ Since that time there have accumulated a large amount of confirmatory data and reports of experiments from over the world that this concept is correct. The purpose of this paper is to summarize this evidence and to make further suggestions concerning the use of some of these drugs, particularly since new preparations are being introduced constantly and at least one of them (sulfanilamide) can be definitely added to the list of offenders.

AMINOPYRINE

The incrimination of aminopyrine in the production of neutropenic diseases is based, first, on geographic studies which show that the incidence of the disease closely parallels the use of the drug; second, on the fact that the incidence is higher for the groups of the population that are the most habitual users of the drug; third, on the collection of records showing that in a large majority of patients with agranulocytosis the disease has followed the administration of the drug, and, fourth, on the administration of aminopyrine to an occasional patient who has recovered, with consequent reproduction of the disease. The fourth type of evidence adds conclusive proof that this drug is capable of producing agranulocytosis in an occasional person.

In 1935 Kracke and Parker² summarized the relationship between agranulocytosis and aminopyrine and collected 153 reported cases of agranulocytosis which had followed the use of aminopyrine. In 1937 Plum,³ in the most comprehensive review of the disease that has yet appeared, collected 267 cases in which it had apparently followed the use of aminopyrine.

The evidence incriminating this drug has been supported by clinical experiments in which patients who have recovered have been given small doses of the preparation and the disease reproduced in them. Such experiments have been carried out by Madison and

Squier,⁴ Benjamin and Biederman,⁵ Sturgis and Isaacs,⁶ Plum³ and others, and all of them demonstrated that the occasional person who has been fortunate enough to recover from the disease can have it induced a second time by the administration of even a small amount of aminopyrine. Furthermore, in nearly every case in which the disease has developed while the patient was being hospitalized for another condition, it followed the administration of this drug.

Recent clinical experiments of importance are those of Dameshek and Colmes,⁷ who studied four patients who had recovered from the disease. The first patient was given 10 grains (0.6 Gm.) of aminopyrine by mouth, had marked leukopenia and recovered. The second patient was given 10 grains of aminopyrine every two hours for five doses; there was no immediate change in the blood cells, but an attack of agranulocytosis occurred two weeks later. Another patient, after being given 10 grains of aminopyrine every three hours for three doses, presented marked leukopenia. These patients were tested by scratch, intradermal and patch tests, an aqueous solution of the drug being used, but the results were negative. However, when the same solution was mixed with blood serum and permitted to age under refrigeration, the tests with this preparation were positive. Furthermore, a second attack of the disease was produced by the intradermal injection of as little as 0.6 grain (0.04 Gm.) of this "serumized aminopyrine."

This evidence all indicates that the occasional person who acquires the disease after the administration of this drug does so on the basis of a hypersensitivity to it. Therefore it seems reasonable that the patient is allergic to the action of aminopyrine and that the amount of the drug given plays little part in the production of the disease.

This is further indicated by the report of Madison and Squier,⁴ who gave a single dose of aminopyrine to each of two patients, with marked depletion of the granulocytes, and the report of Benjamin and Biederman,⁵ who produced marked leukopenia with one dose of the drug.

An important and conclusive link in the incrimination of this drug is found in the recent report of Plum,³ in which he showed the incidence of agranulocytosis correlated with the use and sale of aminopyrine in

Denmark through the years from 1925 to 1936, as summarized in the accompanying chart.

From this chart it will be seen that the consumption of aminopyrine in Denmark before the disease made its appearance was practically nil and that there was a gradual increase in the use of aminopyrine paralleling the increasing number of cases of agranulocytosis, the peak being reached in 1934. At that time the use of the drug was practically abandoned, and the disease disappeared. Plum³ concluded from his studies that aminopyrine was by far the most frequent cause of agranulocytosis in Denmark.

Many workers have endeavored to reproduce agranulocytosis in lower animals by the injection of aminopyrine and related compounds, but their experiments in general have been unsuccessful. My associates and I have injected aminopyrine in solution into rabbits, guinea pigs, dogs and rats and have fed the drug by mouth to a large number of animals but have been unable to produce a marked depression of the leukocytes in any of them.

Stenn⁸ has administered the drug by various routes to a total of 120 animals, including rabbits, guinea

Chart showing practically complete disappearance of agranulocytosis from Denmark after the importation of aminopyrine was prohibited (from Plum³). The solid line indicates the number of cases of agranulocytosis, the dots and dashes the sale of aminopyrine from importing firms and the broken line the estimated total consumption of aminopyrine.

pigs and monkeys, but with no success in producing depression of the leukocytes. On the other hand, we have submitted the drug to an oxidation process such as conceivably might occur in the intestinal tract and have produced moderate leukopenia, but in only an occasional animal. Madison and Squier⁴ reported a marked depression of the leukocytes in only one rabbit of a total of eleven fed tablets of allylisopropylbarbituric acid and aminopyrine (allonal). Miller and Rhoads,⁹ using a total of fifteen dogs, gave some of them aminopyrine by mouth in conjunction with a blacktongue-producing diet and were able to produce acute stomatitis and anemia before these conditions would have developed from an inadequate diet alone, and they found a suppression of maturation of the bone marrow elements.

Climenko¹⁰ measured the amount of response of the leukocytes in rabbits after injection of sodium nucleinate and measured it again after the animals had been given aminopyrine and dinitrophenol. The height of

the response was much less in the drug-fed animals, and study of the bone marrow showed myeloid hyperplasia followed by suppression of maturation, with some degeneration and necrosis and finally aplasia. This would indicate that the bone marrow in its entirety has to be damaged rather severely before evidence of depression is seen in the peripheral blood and that the marrow has a large reserve power.

Many experiments have been done in an effort to show the effect of aminopyrine on groups of normal and abnormal human beings. For example, Rawls¹¹ observed the development of agranulocytosis in four of 400 patients who were receiving aminopyrine in the treatment of arthritis. Davis and Frissell¹² gave 30 grains (2 Gm.) of aminopyrine daily to thirty-two patients for from two weeks to three months with no change in the leukocyte count. In this connection Plum³ said "It has been well demonstrated that amidopyrine given to large groups of people is not followed by the development of the disease unless one of them happens to have the necessary sensitivity to the drug" and "It has been demonstrated that other drugs have no effect on the blood of persons sensitive to amidopyrine and that amidopyrine has no effect on the blood of nonsensitive persons."

There is now general agreement that aminopyrine is dangerous and that its use should be drastically restricted. Thus, Bie¹³ of Copenhagen said "If we want to avoid the risk of producing agranulocytosis, the only way is not to use amidopyrine at all," while Witts¹⁴ of England declared "Amidopyrine is a dangerous drug and all remedies which contain it should be clearly branded as dangerous drugs with the word 'amidopyrine' and not some alias" and Comroe¹⁵ of Pennsylvania suggested "that this drug be dropped from the pharmaceutical armamentarium."

DINITROPHENOL

Dinitrophenol, which has been used mainly in the treatment of obesity, can definitely be included in the list of drugs that produce neutropenic diseases. Hoffman, Butt and Hickey,¹⁶ Davidson and Shapiro,¹⁷ Dameshek and Gargill,¹⁸ Silver¹⁹ and Frank²⁰ have reported a total of seven cases, two of which were fatal. In addition, the drug is known to produce cataracts in an occasional patient, so that its use in the last two years has been curtailed to a considerable degree and reports of agranulocytosis following its use have become more infrequent.

ARSPHENAMINE

Plum has reviewed the literature of the neutropenic diseases following the administration of arspenamine with and without preparations of bismuth. In fourteen

cases the hematologic defect was limited to the granulocytes and there was no anemia or sign of hemorrhagic diathesis. Furthermore, occasional reports, such as that of Blew,²¹ indicate that this drug does produce in an occasional person a hematologic and clinical syndrome that is indistinguishable from agranulocytosis. He reported this syndrome in three young white males, one of whom had received sixty-eight injections of neoarsphenamine, another a large number and a third only three.

The depressing effect of organic arsenical compounds on the bone marrow elements has long been recognized, but it should be borne in mind that these drugs are capable of producing hematologic defects limited to the granulocytes and therefore agranulocytosis.

COMPOUNDS SIMILAR TO AMINOPYRINE

As soon as the dangers of aminopyrine had become generally recognized it was to be expected that certain pharmaceutical companies would produce similar compounds in which very slight chemical changes were

meter. This experiment is important because it indicates that the person who is sensitive to aminopyrine is also sensitive to novaldin, though this was to be expected because the two preparations are so nearly identical.

SULFANILAMIDE

This remarkable drug, which has proved to be of so much value in the treatment of beta streptococcus infections, is not without its dangers to the blood. These dangers include the development of methemoglobinemia and cyanosis, acute hemolytic anemia and agranulocytosis. I have found eleven cases of agranulocytosis in which the disease apparently followed the administration of sulfanilamide. These are summarized in table 1.

It will be noted that these cases have all been reported since April 1937 and that over half of the patients were young adults. In every instance a large amount of drug was administered (from 40 to 50 Gm.) before the disease made its appearance. This indicates that the mechanism of granulopoietic depression may

TABLE 1.—Agranulocytosis Following the Administration of Sulfanilamide

made so that the therapeutic effect would be as nearly identical with that of aminopyrine as possible and yet the preparation could be given another name. An example of such compounds is that marketed under the name of novaldin. This preparation has the same chemical formula as aminopyrine except that one of the methyl groups attached to the amino nitrogen is replaced by the sodium salt of methyl sulfonic acid.

Agranulocytosis following the administration of this preparation has been reported by Klumpp²² and by Benjamin and Biederman.²³ Ironically enough, Klumpp's patient took this preparation because his physician warned him against the dangers of aminopyrine. Benjamin and Biederman gave 10 grains of novaldin to a patient who had recovered from agranulocytosis which had followed the use of aminopyrine. Within eight hours the clinical symptoms of the disease developed, including a leukocyte count of 2,800 per cubic milli-

be different from that following the administration of a single dose of aminopyrine. In practically all these cases the leukocyte count fell to extremely low levels, with complete disappearance of the neutrophils. The usual clinical symptoms followed, and death occurred in nine of the eleven cases. In nearly all of them the administration of other leukocyte-depressing drugs could have been eliminated.

Therefore, on the basis of these reports, sulfanilamide can be added to the list of drugs that are capable of producing agranulocytosis. Furthermore, it should be borne in mind that because of the increasing use of this drug there will probably be an increasing number of cases in which the disease will follow its administration. This is especially true because the preparation can be purchased by the public in drug stores and used widely without medical supervision. Unfortunately in this connection it is similar to aminopyrine. It is reasonable to assume that the market will shortly become flooded with patented remedies containing this drug and that the dangers of agranulocytosis will become more accentuated.

I have observed two patients in whom the disease developed after the administration of sulfanilamide.

23. Benjamin, J. E., and Biederman, J. B.: Agranulocytic Leukopenia Induced by a Drug Related to Aminopyrine, J. A. M. A. 107:495 (Aug. 15) 1936.

One recovered, but the other died after the leukocyte count had fallen to 2,700 per cubic millimeter with a total absence of granulocytes.

It should be emphasized that sulfanilamide also produces a severe type of acute hemolytic anemia in many patients, the red cells occasionally being hemolyzed to the extent of from one-half to one million cells a day. Also, in some patients sulfanilamide produces a marked stimulation of the leukocytes, which may or may not

† Hematologic depression limited to granulocytes only.

‡ Hematologic depression not limited to granulocytes.

be preceded by a moderate depression. I have observed six such patients being treated for various infectious states; the leukocyte counts reached alarmingly high figures during convalescence from the disease (74,000, 56,000, 40,000 and 25,000, with a marked granulocytic shift to the left). This indicates that sulfanilamide produces in some patients a depression and in others a stimulation of leukopoietic activity.

OTHER DRUGS SUSPECTED OF CAUSING AGRANULOCYTOSIS

In addition to the drugs discussed, which are unquestionably capable of producing the disease, certain other preparations have been suspected by various writers. These include antipyrine, which is the chemical precursor of and closely related to aminopyrine. Groen and Gelderman²⁴ have reported two cases in which agranulocytosis followed its use. Acetanilid as a causative factor has been suspected by Watkins²⁵ and Hudnutt,²⁶ and I have observed a classic attack following the prolonged administration of a patent remedy known as "Dr. Mile's Nervine," the essential ingredient of which is stated to be acetanilid. Acetophenetidin (phenacetin) has been named as the probable causative factor in two instances by Kracke and Parker² and in one by Costen.²⁷

Shapiro and Lehman²⁸ have reported agranulocytosis in one patient who was being treated with cinchophen (atophan). Quinine has been suspected as being causative in at least four instances. Zia and Forkner²⁹

treated a large number of patients for kala-azar with a proprietary preparation of pentavalent antimony compound (neostibosan), and agranulocytosis developed in eight. Plum³ has reviewed the literature concerning the danger of gold salts and collected nineteen cases in which agranulocytosis apparently followed the administration of this class of drugs. All the preparations that are known to be capable of producing agranulocytosis and those suspected of producing it in rare instances are listed in table 2.

ALLYL-ISOPROPYL-ACETYL-CARBAMIDE (SEDORMID)

Sedormid is a preparation that has become widely advocated for the relief of pain. Although it has not been reported as a cause of agranulocytosis, it has been reported as the causative factor in eleven cases of thrombocytopenic purpura³⁰ and is included here as another preparation capable of depressing the thrombocytic elements of the marrow with little effect on the leukocytes. This preparation has been termed non-acceptable for inclusion in New and Nonofficial Remedies and should be used with caution.

THE INCIDENCE OF AGRANULOCYTOSIS

In an effort to determine whether or not agranulocytosis is becoming less frequent in the United States, I have procured data from the United States Bureau of Vital Statistics relative to the deaths reported from it within the years 1934, 1935 and 1936. The figures for those years as well as for 1931, 1932 and 1933 are shown in table 3.

It will be noted that there has been very little change in the yearly number of deaths reported during the past six years. However, death reports are not a reliable index to the incidence of the disease. It can

reasonably be assumed that in the past three years recognition and diagnosis of the condition has become far more frequent than in preceding years. However, it could be claimed that the number of cases is larger now and that more patients recover because of better methods of treatment. It has been my experience that the condition is now rarely seen in the southeastern part of the United States.

A study of the report of the Bureau of Vital Statistics shows a decreased incidence of the disease in prac-

tically all the larger states, as shown in table 4. In this connection I have solicited the opinions of several hematologists in different geographic areas of the country. There seems to be general agreement that the disease is not observed as frequently now as during recent years; this opinion is shared by Custer and Fitzlugh of Philadelphia, Heck and Watkins of Rochester, Minn., Parker of Boston, Sturgis of Ann Arbor, Mich., Haden of Cleveland and Cannon of Chicago.³¹ Madison stated that the disease has increased recently around Milwaukee, with some attacks apparently caused by sulfanilamide.

Such statistics as are available from the larger medical centers show a high peak in the incidence during the years 1933 and 1934, with a decrease up to this time, although no institution has had a sufficient number to make figures of any considerable value. Sturgis states that agranulocytosis did not commonly exist before 1922 and then had an increasing incidence, which reached its peak about three or four years ago, followed by a decline in frequency; this is affirmed by observations in large clinics in which all patients have routine blood examinations.

In view of such fragmentary evidence it seems logical to assume that agranulocytosis is decreasing in incidence, in particular that which follows the administration of aminopyrine. However, in the future this decrease may be counterbalanced by an increasing number of attacks following the administration of sulfanilamide. In view of Plum's report from Denmark, in which it is clearly shown that the incidence of the disease in that country closely paralleled the consumption of aminopyrine, there can be little doubt that the decrease in this country has been dependent on the amount of aminopyrine consumed.

Even if it is possible for all physicians to cease using aminopyrine the disease will not disappear as long as the public is able to purchase this drug over the counter in drug stores. There is much evidence to indicate that the administration of aminopyrine is being curtailed by some physicians. However, in the last case of agranulocytosis that I observed the disease followed the prolonged administration of amytal compound, yet the physician in charge assured me that he had not used aminopyrine in the treatment of this patient because he was cognizant of the dangers of that drug. Apparently he did not know that amytal compound is a mixture of aminopyrine and a barbituric acid preparation. This illustrates the deplorable tendency to prescribe drugs without knowing what they contain and indicates the extent to which pharmacology is dominated by pharmaceutical manufacturers. Aminopyrine is still included with many other preparations in compounds that have been given a variety of names, few of which indicate the presence of the drug. A list of such preparations is shown in table 5. This is an incomplete list and does not include patented remedies for the relief of pain, whose virtues are so loudly extolled over the radio and through other advertising mediums. No doubt agranulocytosis will continue to follow the administration of aminopyrine from three sources: first, from the occasional physician who prescribes it; second, from physicians who unknowingly use it when it is incorporated with other pharmaceutical agents, and, third, from the purchase of proprietary and patented remedies from drug stores by the patients themselves.

In an effort to control the incidence of agranulocytosis the physician should refrain from the use of aminopyrine or analgesic agents that contain it; second, he should warn his patients against the dangers of self-medication, particularly the purchase and use of pain-relieving remedies for which the formula is not available; third, the physician who is using agents such as sulfanilamide in the treatment of severe infectious states or is using arsphenamine and other organic arsenicals should watch the patient carefully for signs of possible hematologic depression by frequent studies of the blood; fourth, the physician should take an active part in the program of public instruction relative to the dangers

of these preparations, for only if he does so can the public become informed as to these dangers. Certainly it will not get this information from drug stores and pharmaceutical manufacturers.

CONCLUSIONS

1. The cause of most agranulocytosis is now definitely established.
2. The disease has practically disappeared from Denmark because aminopyrine is no longer used in that country.
3. Approximately 80 per cent of drug-produced agranulocytosis is caused by the administration of aminopyrine or one of its compounds, with a lesser percentage being caused by the administration of dinitrophenol, arsphenamine, sulfanilamide, and novaldin.
4. The disease is decreasing in incidence in the United States, probably because of the more cautious use of aminopyrine by the medical profession.
5. The number of cases of agranulocytosis from the use of sulfanilamide will probably increase in the future, particularly if this drug is incorporated in patented remedies and indiscriminately sold to the public under noninforming names.
6. Physicians should attempt to prevent this disease by caution in the use of these drugs, by instruction of patients concerning their purchase in drug stores and by programs of public instruction.

THE PRESENT STATUS OF THE SERUM
THERAPY OF LOBAR PNEUMONIA

M. A. BLANKENHORN, M.D.

CINCINNATI

It is not often that the Section on Practice of Medicine requests a report on the present status of the treatment with a well known remedy of a common acute illness. Generally the best remedy soon becomes the most popular, and all physicians quickly learn which one that is. Such, however, has not been the case in the treatment of pneumonia. Apparently the recent interest in the serum treatment of lobar pneumonia has expressed itself in so many forms, other than in curing patients, that one may well ask questions about merit and popularity.

It takes a bold person to judge merit and popularity in a problem that vexes most of the medical profession in an issue that is changing with great rapidity. It is impossible to say very much in finality now. However, after a number of years of personal experience with the serum treatment of pneumonia and after a very thorough search of the current literature, I find that enough information is at hand to warrant a consideration of the present status.

A good many years of my experience have been with slow methods of pneumococcus typing and with treatment using unrefined serum of low potency. But in the past three years, i. e., from October 1935 to April 1938, my associates and I at the Cincinnati General Hospital have studied slightly more than 1,000 cases, in 230 of which potent serum was used. The fatality rate in the serum treated group was 8.2 per cent.¹ The expected fatality in this hospital and under the same circumstances of medical care as judged by 318 cases (not treated) of the same types was 34 per cent. This is a reduction of 76 per cent in fatality rate. We have treated type I and type II pneumonia mainly and these only in the early stages, i. e., before the end of the fourth day of sickness. For type I and type II pneumonia this reduction in fatality rate at the Cincinnati General Hospital just about describes the merits of serum treatment wherever it has been used consistently in early cases that are accurately typed for specificity.

Similar merit has been reported from (what should be called) the pneumonia centers in New York and Boston hospitals. In two states that have pioneered in the use of serum in the home as well as in the hospital the results are not very different. This merit of serum treatment for type I and type II pneumonia is described in all the standard textbooks of medicine of recent date and in up-to-date works on treatment. The superiority of serum treatment over all other cures should no longer be doubted.

In addition to the reports from two Eastern hospitals which have been most quoted, I find eighteen separate reports (all with adequate controls) from Ohio, Michigan, Connecticut, Pennsylvania, Canada, England, Scotland and Denmark, all attesting a 50 to 60 per cent reduction (ours is 76 per cent) in mortality rate for type I pneumonia and from 40 to 50 per cent reduction for type II pneumonia.

There is, however, considerable variation in the actual and final figures, so that if the worst results with serum in one place are compared with the best results without serum at another place, no great merit is seen in serum treatment. Such a method of estimating merit is entirely fallacious, for adequate controls are possible and have been published. I could find no report of completely unsatisfactory results from serum, save only of certain experimental serums that are not recommended for general use. It is true that serum treatment in its present form (i. e., with rapid accurate typing and potent refined serum) has been evaluated in but a few localities; but where it has been tried it is found to be good. Whether one can say good enough for all localities depends mainly on the types found in each locality. To arrive at this estimate of merit I have searched 184 current journal articles, mostly from January 1937 to the present, all recommending the use of serum.

USE OF PNEUMOCOCCUS SERUM

How popular is this treatment; i. e., how extensive has been the use of antipneumococcus serum? To judge from reports in current literature only a few individuals and a few hospitals have actually made general use of it. A questionnaire of hospitals conducted by the American Medical Association² showed that very few large municipal hospitals (where the patient ill with pneumonia is most likely to go) were typing the pneumococci in their cases of pneumonia. Questions were asked of 4,565 hospitals (2,595 hospitals replied, and only 1,850 hospitals reported being equipped to type).

A survey of my own³ on the distribution of serum for the first eleven months of 1937 shows that from an estimated number of 160,413 cases, serum was provided for 34,185 cases of type I and type II pneumonia combined. This estimate of the number of cases treated is based on the information that 3,418,500,000 units of serum was sold. Using 100,000 units as an average for one patient, we find that 34,185 patients with type I and type II pneumonia (or 21 per cent of the estimated total number of cases of these types) received serum treatment in the first eleven months of 1937. This estimate of the annual number of cases of type I and type II pneumonia, i. e. treatable types, was furnished by Dr. McGill of the United States Public Health Service in a report in 1937.

Considering the complete want of any other specific for pneumonia, there is still a considerable gap between merit and popularity (only 21 per cent treated). It is in contemplation of that gap between merit and popularity that many of the facts are to be found that are important in making progress toward pneumonia control. To me it is apparent that, wherever specific serum is being used, accurate bacteriologic diagnoses are being made and accurate vital statistics are being accumulated. By contemplating the present status of serum therapy, much may be learned about pneumonia control. If all the obstacles in the way of early diagnosis and exact bacteriologic diagnosis (typing) were understood and overcome, the progress of pneumonia control would be much more rapid.

In May 1938 THE JOURNAL published the special report of the Pneumonia Advisory Committee of the

Read before the Section on Practice of Medicine at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

3. Data on the distribution of serum for 1937 were supplied through the courtesy of Dr. W. T. Harrison of the U. S. Public Health Service, the National Drug Company, E. R. Squibb & Sons, Lederle Laboratories, Inc., Eli Lilly & Co. and Gilliland Laboratories.

U. S. Public Health Service to the Surgeon General.⁴ It was not a lengthy report, but it contained forty-nine specific recommendations in the way of studies to be made, facts to be found, experiments to be done—mainly bacteriologic—and a few social experiments as well. All these recommendations are based on the new knowledge of pneumonia that may come from the wide use of complete typing.

SUITABILITY OF SERUMS FOR GENERAL USE

Are the present serums suitable for wide and popular use? The answer is yes, if the type incidence is the same all over the country and if typing facilities are available. The actual facts in the matter of type distribution are meager, and but few cities have done the work necessary to learn what the true type incidence may be. New York, Massachusetts, Connecticut, Pennsylvania, three cities in the Middle West (Detroit, Cincinnati and Minneapolis), one on the Pacific Coast (San Francisco) and three in the South have published significant observations on type incidence. Eight large cities of the Eastern and Northern United States show from 43 to 66 per cent for the combined treatable types, I and II. But it has been generally said that upward of 50 per cent of cases are due to pneumococci of types I and II; but, so far as the literature concerned shows, 50 per cent is too high. Meanwhile other serums have been added, thus increasing greatly the so-called treatable types. Especially in the South does this rule of 50 per cent fail. Reports from four large Southern cities show that cases of type I and type II pneumonia combined range from 19 per cent to 35 per cent. Sometimes there is a considerable fluctuation as may result from a change in the plan of typing. I find that when typing is done only to search for pneumonia of types I and II, in order to ascertain whether or not serum treatment is indicated, the results may be quite different from those in laboratories charged with complete typing regardless of the hope to treat. In the one instance the laboratory is satisfied to report whether or not the physician has type I or type II pneumonia to treat, whereas with complete typing the laboratory must tell what type actually is present. This additional responsibility on the laboratory has made for thoroughness, which may greatly revise the ideas about type incidence. For instance, in one city of the South the incidence of type I and type II pneumonia combined had apparently changed from 5 per cent to 50 per cent in two years.

Another prerequisite to popular use of serum therapy is accurate typing. There has been but little use of serum reported without typing even where bivalent serum of pneumococcus type I and pneumococcus type II combined is employed. How accurate then is typing? In good hands the rapid, direct method of Neufeld seems to be very accurate. In a recent book of great merit, the late Dr. Benjamin White⁵ concluded that by this method "there should be few cultures that cannot be classified in the thirty-two fixed types." The Neufeld method applies equally to sputum, but broth cultures and mouse inoculations are frequently needed to check sputum analysis and occasionally to analyze sputum where the direct method fails. The Neufeld method, although simple and easy to learn, requires practice and patience.

Dr. James Ruegsegger, pneumonia fellow in the Cincinnati General Hospital, has trained a large group of typers for the Ohio State Department of Health as well as every one of the numerous assistant residents who came to our medical service. He finds that these students can master the technic in a week's intense work and relies on these residents for a considerable amount of emergency typing. When sputum is not obtained promptly, we use cultures made from throat swabs and find, as do others, that although slower than direct sputum typing it is a satisfactory method. Blood cultures are found very useful for routine serum therapy and in some circumstances are absolutely essential for accurate knowledge needed for treatment. Blood cultures check the accuracy of sputum typing, especially in cases in which multiple infections may occur. Blood cultures are of aid in calculating dosage, and most writers recommend that a double dose of serum be given to patients who have bacteremia.

CARRIERS

What about the carrier state and the difficult task of deciding whether a mouth organism is important or unimportant? That problem is solved by the combined experience of the bedside doctor and the typer. The gross appearance of the sputum, the scarcity of other organisms and the method of sputum collection or of throat swabbing must all be added to intelligent bedside guessing in a manner rarely practiced in any other clinical laboratory consultation. Prompt and accurate typing is absolutely essential to successful serum treatment and requires an intimate working relation between laboratory and bedside doctor that is rarely to be found, save only where some pneumonia enthusiast has worked for several years. This teamwork must be rehearsed in advance of the onset of the disease. Want of this consultation service spells failure unless the clinician does all his own typing, which is seldom possible. Laboratory delay or confusion can wreck any so-called pneumonia program.

EFFECTIVENESS OF SERUM

Is specific serum administered when accurate typing has been done generally successful? For type I pneumonia, when given early and in large doses, the answer is yes. It is so uniformly successful that if the patient does not improve one should suspect a mistake in typing or the presence of a complication, usually empyema. For type II pneumonia, even with large doses results are not so favorable, but mortality is reduced from an expected rate of 40 per cent to about 20 per cent if treatment is instituted early in the course of the disease. The effectiveness of serums for pneumonia of types V, VII and VIII seems midway between that for types I and II as reported from six separate hospitals during 1937. In our own series for 1937-1938 (which is the time we have had such serum) the result was as good as in type I pneumonia.

In all reports for all serums, the necessity of early treatment is clear. It also appears that the practice of early treatment with serum will eventually effect a definite change in the habits of doctors caring for patients with pneumonia. In diagnosis, the emphasis now will fall on history, symptoms and faint physical signs. Most of the technic of diagnosis, including x-ray as ordinarily taught and practiced, is inadequate for early diagnosis and to recognize complications.

SAFETY

Is serum safely and easily given? Since serum for adults must be given intravenously in large doses as early as possible, certain dangers must be offset by precautions. The Massachusetts Department of Public Health found four deaths among 1,313 treated patients in which the death could be ascribed to the serum. About one fourth of the patients of this series were treated in homes in Massachusetts. In our series there has been one such death among 230 treated patients. In our particular instance, obvious warnings were not seen and understood by the intern giving the serum. We practice as a routine the methods of testing for sensitivity which are accepted everywhere and recommended by Lord and Heffron⁶ as well as by Bullowa⁷ in textbooks on the serum treatment of pneumonia. We have abandoned the methods of desensitizing; but we do, in doubtful cases, give a test dose intravenously and watch the blood pressure for a drop that might presage a dangerous shock.

As to other types of serum, i. e. other numbers, especially rabbit serum, I am not so sure, but I think that in the hands of skilful physicians most patients can be treated safely with any form of serum. I have searched thoroughly most of the state journal literature up to and including May 1938 and I do not find any account of serum accidents or any warnings against the present methods now advanced, except that the State Department of Health⁸ in New York did issue a warning in *THE JOURNAL* about the general use of rabbit serum.

I find a trend to shorten the intervals between doses and to raise the dose, especially for type II pneumonia. We now treat many of our patients with but two doses, one of 20,000 units and an hour later one of 60,000 or 80,000 units of type I. For type II pneumonia we generally give 20,000 then 60,000, 60,000 and 60,000 at hourly intervals.

In all cases in which blood cultures are positive we administer, as does every one, twice the usual dosage. This supplementary dose is usually given on the following day, as blood cultures require from twelve to twenty-four hours for incubation. We do not assign to an expert the giving of serum. All our interns and residents give it as a part of the hospital routine. Sensitive or doubtfully sensitive patients are treated by interns but under immediate supervision of the fellow in pneumonia. In passing I may describe our hospital as a city hospital without a special pneumonia service and without many of the facilities that university hospitals enjoy. The cost of the serum is borne by public funds, but the laboratory is maintained and the director provided by private funds.

COMPLICATIONS

What about serum therapy and complications? Early successful serum treatment prevents and cures pneumococcic septicemia and in this manner reduces the incidence of suppurating complications. If such suppuration has already started before serum treatment has been completed, horse serum is probably of no value. This want of value in pneumococcic suppuration may not be true of rabbit serum. Even with large doses, a considerable percentage of serum failures is found to

be due to undiscovered empyema. All writers with experience emphasize the importance of searching out early empyema. We have learned that serum is of no value in endocarditis, and we were unsuccessful in treating pneumococcic meningitis.

SUMMARY

Complete typing of all cases, through the entire thirty-two types, is the keystone of serum treatment and may provide the necessary information leading to the prevention of pneumonia.

In parts of the United States where typing has been practiced, treatable types comprise more than 50 per cent of all cases of pneumonia, save only in certain districts of the South. Now that other therapeutic serums (V, VII, VIII and probably many more by the device of rabbit serum) have been developed, a much higher percentage will be treatable.

Neufeld typing of the sputum and cultures of various body fluids is a rapid and accurate method of bacteriologic diagnosis of pneumococcus types.

The selection of patients for efficient and satisfactory treatment requires early diagnosis by the physician and intimate consultation with the bacteriologist. Serum must be given in adequate dosage by vein, and a double dose must be given when blood cultures are positive. Serum must be injected slowly after sensitivity tests are found negative, but the entire dose should be given during the first twenty-four hours. Serum accidents have been extremely uncommon and the danger of reactions early and delayed should rarely preclude treatment.

Refined and concentrated horse serum for type I and type II pneumonia is a well established and satisfactory remedy. When given during the first twenty-four hours it is a specific comparable to the best specific biologic remedy, save only diphtheria antitoxin. When given within the first four days of the disease, the mortality rate of pneumonia may generally be reduced more than 50 per cent. In our experience of three years the mortality was reduced 76 per cent.

Until 1937 the use of serum treatment, as judged from published results, was restricted to a few places—Massachusetts, New York, Maine, Connecticut, Ohio and Michigan. In 1937 approximately 20 per cent of patients with type I and type II pneumonia in the United States were treated with serum.

Cincinnati General Hospital.

ABSTRACT OF DISCUSSION

DR. EDWARD S. ROGERS, Albany, N. Y.: In regard to the arbitrary selection of a period of four days from the onset of the disease as being the crucial interval for serum treatment, our experience in New York State has added a little further information. In the specific treatment of 2,027 type I cases, we have found that we can extend that period of usefulness to include the fifth day, the case fatality rate for cases treated on that day being, roughly, 16 per cent. One must be cautious in attempting to predict the incidence of pneumonia and particularly of individual types in the anticipated experience of any particular community. I am not sure how Dr. McGill, whom Dr. Blankenhorn quotes, derived his figures, but the basis on which such calculations usually are made is rather questionable. Dr. Blankenhorn has suggested such caution and also the futility of assuming that the type incidence once established for any given area will necessarily remain the same for that area. Dr. McLaughlin of Pittsburgh has told me that in his experience in the past three years he has encountered a change in the incidence of type II pneumococcus pneumonia from about 5 per cent to

about 35 per cent. In New York State we have observed massive shifts in the prevalence of type specific pneumonia in a number of areas during the past few years. The use of repeated sputum specimens is unquestionably with emphasis. A patient treated early and adequately with specific serum who does not respond to that treatment within a period of from twelve to eighteen hours may well be subjected to a complete bacteriologic reexamination. Under such circumstances another type of pneumococcus often may be found. In this respect the proper use of blood cultures will also prove of great value. Time does not permit a discussion of the problem of sensitivity to horse serum, though I imagine it might interest this group particularly. I would like to say, however, that we are finding the significance of the skin test and the ophthalmic test rather difficult to understand in relation to reactions subsequently encountered. In our type I experience, however, fatalities in any way related to serum administration, whether anaphylactic or more vague in nature, were encountered in less than 0.5 per cent of all cases. There were no deaths from chill or thermal reactions in the entire series.

DR. FRANCIS G. BLAKE, New Haven, Conn.: One of the most frequent questions encountered is What shall be the size of the initial dose? I noticed that Dr. Angevine included 50,000 units within the range of a large dose. I would consider 50,000 units a quite small initial dose, as we rarely use less than 100,000 units. The second important question is How late in the disease is it worth while beginning the use of anti-pneumococcus serum? I should like to ask Dr. Blankenhorn his opinion on that. The third important question that often arises is How long shall serum therapy be continued in a patient who has not shown clinical response after 200,000 or 300,000 units? It would be interesting to know Dr. Blankenhorn's opinion from his own experience.

DR. JAMES L. DUBROW, Des Moines, Iowa: It is important to know, when dealing with a case of pneumonia, how the diagnosis is made. Emphasis was laid on the bacteriologic examination of the sputum. However, some patients may be carriers, or the sputum may be scanty. In my opinion a chest roentgenogram shows important early signs in suspected cases of pneumonia. In some cases of early pneumonia physical examination may disclose a rale or two and one may think the chest is normal, yet the stereogram shows a patch of haziness which is a possible sign of beginning pneumonia. For corroboration in doubtful cases the chest roentgenogram should be repeated some hours or a day later, when an opacity may be shown occupying one or two lobes. Furthermore, the history of the case should be taken into consideration. Highly significant is the onset of the illness. Some claim that in lobar pneumonia atelectasis is demonstrated on the roentgenogram. The question of atelectasis is closely bound up with that of bronchostenosis. If the patient has not had a sudden acute illness, one may be dealing with a bronchogenic tumor. It may not be a case of pneumonia at all. Early blood cultures should be made, especially when the sputum is scanty or the sputum typing gives contradictory results. In such cases it is well to do a lung puncture, remove a little serum and have it examined bacteriologically for pneumococci. Once one has decided that one has a case of pneumococcal pneumonia and knows the type causing it, the question of serum therapy arises. It is well to take into consideration the leukocyte response, temperature rise and how ill the patient looks. Before administering serum it is important to determine by history, skin and conjunctival tests whether the patient is allergic. I have had cases of type I pneumonia in which the patients (some allergic) got along nicely without serum.

DR. M. A. BLANKENHORN, Cincinnati: I am indebted to Dr. Rogers for pointing out that the fourth day is not critical and that one should include the fifth day. Selection of patients was determined by economic reasons rather than epidemiologic ones. It was not possible to afford the serum for everybody, so the early cases, in which the most good could be done, were treated and the fourth day was arbitrarily chosen. Dr. Rogers emphasized the importance of typing. There seems to be a hope in wishful thinking that we won't need to type because eventually a single serum or chemical will do for all types. Certainly the trend now is for type specific serum and the

"typing" of patients for treatment absolutely essential. Dr. Blake asked a pertinent question with regard to the size of the initial dose. This dose is 20,000 units. I regard that as a testing dose. Then in one hour after the first dose I give the second dose, which may be 60,000 units or even 80,000 units, so the entire 100,000 is given within two hours. I expect to get the entire dosage in the vein within a few hours, unless the blood culture is found to be positive, in which case the repeated dose, which is equal to the first dose, is given within twenty-four hours. "How late to start treatment?" I have no opinion on that. Late treatment was not given because we couldn't afford it and because the importance of coming into the hospital early has been emphasized. "How long to continue treatment after 200,000 or 300,000 units has been given?" I have not set a time. I rarely give serum after the second day, unless blood cultures are positive. I generally stop on 300,000 units, and I have had so few failures that the question of going on with more serum rarely arises. When it does, complications are looked for. Early cases, of course, are being treated. Dr. Dubrow answered his own question when he asked about the diagnosis and then immediately mentioned the history. I think that for early recognition of the disease the history is more important than physical signs. The roentgenogram is of importance only in confirmation. The patients in our medical service are examined repeatedly and we think the most important physical sign for early diagnosis is the crepitan rale. The history and sputum are of a great deal more importance.

APNEA OF THE NEWBORN AND ASSOCIATED CEREBRAL INJURY

A CLINICAL AND STATISTICAL STUDY

FREDERIC SCHREIBER, M.D.

DETROIT

It is with some temerity that a neurologic surgeon undertakes to address an obstetric section on the subject of cerebral injury in the newborn. The two specialties have a common responsibility, however, to the child showing clinical evidence of such injury, and if either can contribute anything to reduce the number of these tragedies a critical analysis of the subject is certainly desirable.

The evidence obtained during this study indicates that cerebral asphyxia at birth may cause permanent degenerative changes in the brain with clinical neurologic manifestations. The correlation between recent neuropathologic, pharmacologic, physiologic and obstetric observations may be traced. From experience and research it is found that most cases of cerebral birth injury are associated with apnea at birth.

The significance of the association may be clarified by means of a schematic diagram showing the relationship between the stages of oxygen deficiency and results of that deficiency and the possible degrees of cerebral damage from a deficient oxygen supply. The causes and effects of various degrees of fetal anoxemia are represented in figure 1. The circle represents a wheel the segments of which turn only to the left. The hub of the wheel is the respiratory center in the

The Research Laboratory of the Children's Fund of Michigan assisted in the production of this paper.

Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article will appear in the author's reprints.

Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

Constructive criticism and encouragement were given by many of my colleagues, in particular Drs. George Kamperman, Nathaniel Gates, Joseph B. De Lee, Norman Miller, Ward Seely, Lewis Daniels, Owen Foster, Nathan B. Eddy, Louise Eisenhardt, Gabriel Steiner, Frank Murphy, David Levy, Edgar Mahter, W. C. Cole, W. L. Brosius and the research departments of Parke Davis & Co. and Eli Lilly & Co.

medulla. This center, first described by Legallois in 1812, depends for its proper function on the interchange of oxygen and carbon dioxide. The factors that are known to depress the respiratory center are oxygen want, drugs, gases and organic change. The obstetric counterparts of these depressing agents are normal birth trauma, abnormal birth conditions, operative intervention, oxytocics, analgesic drugs and anesthetic gases. The arrows pointing to the respiratory center indicate the degree of depressing effect on the center by these agents in relation to the clinical effect on the newborn.

The quadrants designated as phases I, II, III and IV relate the changing situations in the fetal cerebral oxidation processes. Phases III and IV, especially, concern the neurologist, since these phases include the clinical manifestations of disturbed cerebral function. The line between phases III and IV has been designated as the vital line. This line indicates the division between

if anoxemia is shown to be dangerous in itself. The most vital and rapid effect of anoxemia is on the brain, where isolated groups of cells may quickly die if there is an oxygen want (anoxia) in the tissues. Such localized cell death is irreparable and can be seen microscopically if the baby perishes. However, these localized areas of necrosis resulting from cerebral anoxia do not necessarily cause the death of the fetus or infant. In case of survival the clinical evidences of localized necrotic lesions or their resultant intracerebral scars and atrophy are neurologic disturbances whose pattern depends on the location and extent of the damaged areas.

Since the analgesic drugs employed during labor are a frequent cause of dangerous apnea in the newborn, it seems that, if brain damage is later found in cases in which considerable analgesia has been used, this injury can properly be ascribed, either wholly or in part, to the optional drugs that have been given to the mother in labor.

During a ten year period (Jan. 1, 1928-Dec. 31, 1937) 685 patients were seen in whom a relationship was suspected between the manner of birth and the later neurologic manifestations of damage to the brain. Most of these patients were seen at the Children's Hospital of Michigan, Detroit, and the remainder were seen in consultation. Of the 685 children, 131 were seen because of convulsions, sixty-nine because of spasticity, 130 for mental retardation, 248 because of combinations of these symptoms and the remaining 107 for miscellaneous neurologic conditions.

Cases subject to suspicion of postnatal infection or trauma were excluded from the group, as were those in which congenital or familial factors might have significance in cerebral symptomatology: associated meningocele, harelip, familial feeble-mindedness, erythroblastosis, hemorrhagic disease and congenital heart disease. Finally, the group was limited to those infants born in one

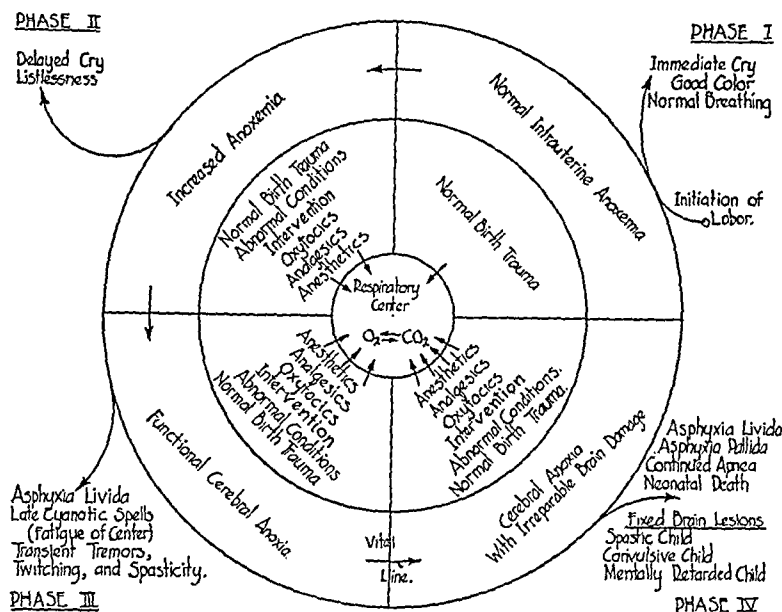

Fig. 1.—Schematic representation of the correlation between the incidence and extent of apnea and the occurrence of cerebral symptoms.

transient neurologic manifestations and irreparable damage to the brain in the newborn.

The "wheel" is set in motion by the initiation of labor. The extent of its rotation before birth varies in every case, depending on the occurrence of such unpredictable factors as the incidence of natural birth difficulties; the weight, second stage metabolism, and blood oxygen capacity of the mother, and, in addition, her individual susceptibility to the drugs and anesthetics employed to abolish pain.¹ The temperature existing in the mother and in her environment during labor and delivery must be considered. A further flip of the wheel by a depressing dose of an analgesic drug may spell the difference between a normal and a permanently damaged baby if the vital line is crossed. It appears to me that the effect of chance, in some of the cases studied in which anesthetics and analgesic drugs have been employed in labor, has been allowed to participate to such an extent as to be somewhat disturbing to the professional conscience.

Since apnea is a clinical indication of anoxemia, it must be regarded as dangerous to the newborn infant

county during the ten year period. These restrictions left 500 cases in the study group.

Study of the records for the group immediately showed that 155 of the babies were born under conditions over which a physician has little or no control: precipitate, breech, twin or premature deliveries. For some cases all the birth data were obtainable—the obstetric difficulties and the oxytocics, analgesia and anesthesia used. In others, although it is known that the mothers were given "shots" and "pills" the amounts are not known. When not available from the birth records, information on the condition of the infant at birth was given by a parent when the child was brought in because of neurologic manifestations. Only histories of apnea were accepted in which the baby was reported as remaining "black" or "blue" for a considerable period after delivery, there were recurring "blue spells," or the infant did not breathe and had to be resuscitated.

The occurrence of apnea in the group of 155 infants born under uncontrollable circumstances (precipitate, breech, twin and premature delivery) is recorded in table 1 in relation to the type of delivery used.

In table 2 the occurrence of apnea is related to the various adjuvants used during the process of childbirth.

1. Schreiber, Frederic, and Gates, Nathaniel: Cerebral Injury in the Newborn Due to Anoxia at Birth, *J. Michigan State M. Soc.* 37: 145 (Feb.) 1938.

The remaining 345 subjects of the 500 were all full term infants; in this group there were no precipitate, breech or twin deliveries. Table 3 presents the relationship between the type of delivery and the occurrence of apnea for all the 345 whose condition at birth was known. Of the 345 infants in this group, 180 were known to have been born in the hospital and 135

posed of precipitate, breech, twin and premature deliveries is greater than in the full term group.

From table 5 it can be seen that the majority of cases in this group (500) showing evidence of cerebral damage presented one factor in common—apnea at birth. The term apnea is used in its broadest sense and includes all cases in which there was delayed

were known to have been born at home; for thirty the birthplace was not recorded.

The incidence of apnea within this group in relation to various forms of adjuvant treatment during childbirth is tabulated (table 4).

In table 5 the data from tables 2 and 4 on the occurrence of apnea are summarized and given in the percentage of those cases about which information was available. The incidence of apnea in the group com-

respiration, asphyxia livida or asphyxia pallida was evident or resuscitation was required. Of the 500 cases analyzed in the tables it may be seen that apnea in some degree was present in approximately 70 per cent of the cases in which the condition at birth was known. Fourteen mothers are known to have received nitrous oxide, 211 received ether and forty-eight received nitrous oxide-ether anesthesia. In the forty-five cases of these two groups (total group of 500) in which

no analgesia or anesthesia was used, 38 per cent showed evidence of apnea at birth or within the first few days. It must be remembered that all these patients are abnormal, with cerebral symptoms. The incidence of apnea in all the full term babies, born spontaneously, without drugs or anesthesia, during 1936 at Herman Kiefer Hospital, Detroit, was 5.76 per cent, approximately one seventh of the occurrence in the neurologically abnormal group.

Apnea indicates the presence of some degree of anoxemia with its attendant cerebral anoxia, but serious

Fig. 2.—Barbiturates and hypnotics in labor; effect on initial respirations of infants.

anoxemia may be present without clinical evidence of apnea. It would seem that apnea is undesirable from the clinical standpoint since it appears in such a high percentage of cases that later show evidence of damage to the brain. Apnea is commonly found in a higher percentage of cases when analgesia and anesthesia are employed in labor than when no analgesia or anesthesia is used.² This fact is graphically illustrated in figure 2, adapted from the work of Irving, Berman and Nelson.³ These authors state that, "all methods [of analgesia] used delayed the initial respiration of the infants to some extent; since a control series of cases in which delivery was effected without any anesthetic showed only 1.9 per cent of infants who did not breathe immediately at birth."⁴

Regardless of the associated conditions in the cases of suspected cerebral birth injury under consideration, the majority were recruited from those infants who did not breathe immediately at birth—a group comparable to those represented by the blacked-in areas in figure 2.

One of the toxic effects of all drugs used to produce analgesia in labor is depression of the respiratory center.⁵ Snyder and Rosenfeld, working with animals, have shown the depressing effect of analgesic drugs administered to the mother on intra-uterine respiratory movements. Such cessation of respiratory movements may be taken as an index of anoxemia, since, according to Haldane and Priestley,⁶ "no existing physical or

chemical method of discriminating differences in reaction approaches in delicacy the physiological response to the breathing." It may be assumed that intra-uterine asphyxia may take place under similar circumstances in the human fetus. A large initial dose of an analgesic drug may depress the respiratory center of the mother to such a degree that a dangerous anoxemia ensues in the fetus, with resultant anoxic changes in the brain. However, the interval between the administration of the drug and the birth of the fetus may be of sufficient duration to allow the respiratory center of the fetus to reestablish itself, even though cerebral damage has already resulted, and the anoxemia that existed in utero is therefore not evident when the infant is born.⁷ Although permanent degenerative cerebral change may have taken place in such cases, the respiratory center itself was probably spared and normal breathing was observed at birth. Anoxemia, however, makes the respiratory center susceptible to fatigue,⁸ and this may be the explanation for the frequent occurrence of late apnea in these cases.

I have applied the term "asphyxia occulta" to the particular group of cases which came with evidence of damage to the brain and in which, during labor, a dose of analgesic drug had been given beyond the ordinary pharmacologic dosage, although the infant's record of birth showed no signs of apnea. This group of patients includes many of the apparent inconsistencies in the correlations between the administration of analgesics and anesthetics and the occurrence of apnea. Apnea of the mother necessarily results in anoxemia of the fetus. Anesthetists generally agree that the cyanosis shown by mothers under the influence of analgesic drugs improves when they come to the birthroom and receive oxygen with anesthesia. Fetal brain tissue, being more sensitive to narcotization, probably is the first to suffer anoxic changes if the drug-induced respi-

Fig. 3.—Maximum drug factor of analgesics administered in any eight hour period during childbirth to mothers of 122 babies who later showed evidence of cerebral damage.

ratory depression is severe enough.⁸ Some mothers have shown permanent cerebral change following analgesic delivery when the child also showed evidence of cerebral damage. In other cases the child apparently showed no evidence of cerebral damage, although the mother showed neurologic symptoms following analgesic delivery.¹

No attempt has been made to determine the exact role of dystocia, operative intervention, intracranial hemorrhage and the use of oxytocics, anesthetics or analgesics and whether these are responsible for cerebral damage at birth.⁹ I wish merely to emphasize the fact that apnea, from whatever cause, may be dangerous to the fetal brain. Cerebral anoxia has been found to cause intracranial hemorrhage even though trauma is not a factor.¹⁰ Drugs that inhibit labor are also a causative factor in the present increased need for intervention.¹¹ Thus, analgesics and anesthetics, which are optional therapeutic auxiliaries, are probably the cause, in some cases, of intracranial hemorrhage—and certainly of increased surgical intervention.

Various drugs and combinations of drugs were used to obtain birth analgesia in this series of cases. In 122 deliveries for which the exact drugs, doses and times of administration are known, the distribution was as follows: morphine alone seven, morphine and barbiturates seven, morphine, scopolamine and barbiturates eleven, barbiturates alone nineteen, scopolamine and barbiturates nineteen, scopolamine alone twenty-eight and morphine and scopolamine thirty-one.

TABLE 5.—Incidence of Apnea in the Two Groups of Cases in Which Data Concerning Apnea Were Available, Tabulated in Percentage, and the Composite of the Two Groups

| | 345 Full Term Deliveries | 155 Precipitate, Breech, Twin, and Premature Deliveries | 500 Composite Group |
|---------------------------|--------------------------------|--|---------------------------|
| Apnea at birth..... | 61.7 | 63.9 | 62.3 |
| Late apnea..... | 8.6 | 11.2 | 9.4 |
| Apnea at birth and later. | 16.8 | 18.5 | 17.3 |
| Total apnea..... | 68.9 | 72.0 | 69.9 |

When barbiturates were used in combination with scopolamine, the dosage that was usually followed was the one that has been described by Irving, Berman and Nelson:³

The initial dose of sodium amytal by mouth was from 9 to 12 grains, depending upon the weight of the patient. This drug was repeated three to four hours later in from 3 to 6 grain doses if indicated. Forty-five minutes after the initial dose of sodium amytal one one-hundredth or one one-hundred and fiftieth of scopolamine was given subcutaneously and was repeated later as soon as the patient began to complain of pain.

The initial dose [pentobarbital and scopolamine] is from $4\frac{1}{2}$ to 6 grains by mouth which may be increased if desired, and it is repeated according to the same indications as govern the use of sodium amytal.

If scopolamine alone was used, the dosage advocated by Daniels and Tamblyn,¹² based on their experience in 453 cases, was usually followed:

One 1/100 of a grain (of scopolamine) is given every half hour for 3 doses and then one 1/100 grain every two hours. . . . The average dose of scopolamine was 5 1/100 grain. The smallest dosage given which resulted in complete amnesia was 2 1/100 grain and the largest dose used in this series was 21 1/100 grain.

Such obstetric dosages¹³ are difficult to reconcile with the ordinary clinical doses as defined by the pharmacologist.¹⁴ The ordinary hypnotic dose of sodium amytal is from 3 to 9 grains (0.2 to 0.6 Gm.) at intervals of not less than six hours. The hypnotic dose of pentobarbital is given as from $1\frac{1}{2}$ to 3 grains (0.1 to 0.2 Gm.), with severe intoxication from doses over $7\frac{1}{2}$ grains (0.5 Gm.).¹⁵ Severe toxic effects with respiratory depression from 3 grains of pentobarbital have been reported.¹⁶

Of scopolamine, Sollmann¹⁶ states in his 1937 manual: "There are great individual variations in the response to scopolamine and therefore in its toxicity. The variable toxicity is due mainly to idiosyncrasy, for it occurs in the purest samples." He further says: "Small doses (1/300 to 1/75 grain) have produced serious poisoning with cardiac and respiratory collapse.

Fig. 4.—Generalized cerebral atrophy in an idiot with asphyxia pallida at birth.

. . . With ordinary individuals it is not safe to exceed 1/120 grain, repeating this smaller dose every six to eight hours if necessary."

The ordinary clinical adult pharmacologic dose of the drugs known to have been employed in this series of cases in which cerebral damage was encountered has been assigned a factor value of 1 for purposes of comparison with other cases in which combinations of drugs were used. If the dose used was greater than the ordinary clinical dose, the factor was increased by the proper multiple (or fraction).

9. Data on this subject were accumulated during the study but must await further analysis before publication.

16. Willcox, William: The Uses and Dangers of Hypnotic Drugs Other Than Alkaloids, Brit. M. J. 1: 415 (March 10) 1934.

If combinations of drugs were used, the combined factors were added. For example, morphine one-fourth grain (0.015 Gm.) (factor 2) and scopolamine $\frac{1}{120}$ grain (0.0005 Gm.) (factor 1) would give a combined drug factor of 3 in this case.

The usual doses of various drugs used have been assigned the factor values given in table 6.

Because of the difficulty in properly evaluating the effect of time, since in most cases the warnings of the pharmacologist regarding the repetition of doses within certain time limits were ignored, I was able to compare the cases only on the basis of the maximum amount of analgesics given in any eight hour period. The drug factors for the 122 patients during the eight hours of maximum administration are shown in figure 3.

It must be borne in mind that this discussion on the effects of drug dosage refers to adults who happen to be in labor. The fact that they are in labor does not protect them against the effects of toxic doses. The usual and most alarming effect is respiratory

expected to respond if orthopedic procedures were attempted. If the cerebral loss was found to be too extensive, the mentally retarded child was regarded as needing institutionalization.

Figure 4 is a reproduction of an encephalogram showing generalized atrophy of cerebral tissue in an idiot born with asphyxia pallida.

MICROSCOPIC CEREBRAL CHANGES IN STILLBORN AND NEONATAL ASPHYXIAL DEATHS

Yant and his co-workers¹⁰ fully described the microscopic changes of anoxic cerebral lesions in animals. These typical microscopic changes of the brain, which Courville¹⁷ later demonstrated in the human being as associated with cerebral anoxia, were found in infants in whom asphyxia has been present for some hours or days. Eisenhardt¹ has pointed out such changes in the brain of a stillborn infant, and more recently Steiner¹⁸ has demonstrated similar "devastation areas" in the brains of newborn infants who perished with evidence of asphyxia (figs. 6 and 7).

Figure 7 shows a section taken from the medulla of an infant who died with convulsions on the third day after birth. There had been numerous apneic spells with cyanosis dating from birth. Dr. Steiner describes the histologic changes:

In the medulla oblongata, involving the dorsal and lateral margin, a circumscribed area is present, the shape of which

Fig. 7.—Necrosis in section of medulla of an infant cyanotic from birth.

depression. If the mother must contend with drug-induced respiratory depression in addition to the natural exigencies of childbirth, the fetus must also, being dependent on the mother for its oxygen supply until actually born, suffer from the same respiratory depression and at the same time go through the intensely traumatic experience of being born.

GROSS CEREBRAL CHANGES ASSOCIATED WITH ASPHYXIA AT BIRTH

The late microscopic changes of cerebral anoxia are death of neural tissues with gliosis.¹⁰ The gross end result is atrophy of the brain. Such atrophy can often be demonstrated by means of the encephalogram. Pneumographic studies were made on 207 of the infants in this series, of which seventy-three showed generalized atrophy, seventy-five showed localized atrophy, thirty-five showed no demonstrable changes in the roentgenograms and twenty-four of the studies were technically of no diagnostic value. These studies were usually made to determine whether the degree of cerebral atrophy was such that a spastic child could not be

TABLE 6.—Factor Values for Usual Doses of Various Drugs

| | Dose, Grain | Factor |
|--------------------------------------|-----------------|--------|
| Morphine sulfate..... | $\frac{1}{8}$ | 1 |
| Morphine sulfate..... | $\frac{1}{4}$ | 2 |

| Sodium amytal..... | 9 | 3 |

is oval and the color paler than the surrounding tissue. The size of this area is 0.6 mm. in length and 0.16 mm. in width. The limits of the lesion are sharply defined and quite regular. This area is characterized by a looser meshwork of the glial ground substance, the spaces between the meshes being empty.

A few ganglion cells are seen which show a very definite process of degeneration as evidenced by homogenization and vacuolation of the cytoplasm, pyknosis and decentralization of the nucleus, which is here located in the peripheral part of the ganglion cell. A nerve cell shadow indicating total degeneration of the cell is also present in this area.

The histologic picture is typical for the first stage of a devastation area. The location of this lesion in the medulla oblongata near the nuclei of the tenth nerve may be of particular significance.

SUMMARY

In a series of 500 patients, seen because of cerebral symptoms, approximately 70 per cent of those whose birth record was available had a history of apnea. There was a history of precipitate, breech, twin or premature delivery for 155 of the 500 infants; 345 were full term infants. In those of the group of 155 about whom data were obtainable, approximately 64 per cent had apnea at birth, 11 per cent had late apnea only and 18 per cent had both early and late apnea. The total incidence of apnea in this group was 72 per cent.

In the group of 345 full term infants, the incidence of apnea in the cases presenting a known history was

17. Courville, C. B.: Asphyxia as a Consequence of Nitrous Oxide Anesthesia, *Medicine* 15:129 (May) 1936.
18. Gabriel Steiner, research professor of neuropathology, Wayne University College of Medicine, Detroit.

at birth, 62 per cent; late, 9 per cent; early and late, 17 per cent, and total, 69 per cent.

The depressing effect, on the respiratory center, of birth analgesics given in greater than pharmacologic doses bears a direct relationship to the degree of apnea. The extent of the apnea has a direct relationship with the severity of the cerebral symptoms after birth. The severity of the cerebral symptoms is in direct relation to the amount of damage to the brain tissue. From these relationships it appears that analgesics given in greater amounts than the pharmacologic dosage may in many instances be the causative factor of fetal anoxemia, with resultant cerebral damage in the infant.

10 Peterboro Street.

ABSTRACT OF DISCUSSION

DR. C. B. COURVILLE, Los Angeles: My interest in asphyxia has been largely in its pathologic manifestations. This study by Dr. Schreiber would seem to strengthen the conception that the lesions of asphyxia are essentially the same regardless of the mechanism or cause of depression of the respiratory and cardiac centers. Subtotal destruction of the occipital (calcarine) cortex as a result of asphyxia can be demonstrated. This cortical area seems to be particularly sensitive to the reduction in oxygen supply. Laminar degeneration is a slightly less advanced type of lesion. Several laminae of necrosis in the cortex tend to fuse, particularly in the superficial part of the convolution. These foci of necrosis tend to occur about dilated blood vessels, which are obviously larger than those in the apparently normal regional tissues. The presence of these distended vessels in the areas of necrosis suggests that stagnation is one of the factors in producing the ultimate effects of asphyxia. It should be said that asphyxia in the newborn is due to excessive depression of the respiratory and at times the cardiac centers, that necrosis of the cerebral gray matter will occur if spontaneous breathing is absent for any length of time, that this necrosis is not demonstrable histologically unless the infant survives for at least thirty-six to forty-eight hours and that this necrosis is probably responsible for many of the residual symptoms in children that survive. As Dr. Schreiber has emphasized, the respiratory center may be dangerously depressed by anesthetic agents and drugs used in relief of pain during delivery as well as by mechanical means. Excessive depression with such agents is probably less likely to occur in well organized clinics than in deliveries in smaller hospitals or in the home.

DR. J. C. LITZENBERG, Minneapolis: Dr. Schreiber has shown that we are too apt to evaluate our results by immediate considerations only, ignoring more remote consequences. Ever since I observed the extremely high percentage of asphyxiated babies in the Freiburg clinic, where Koenig and Gauss developed "twilight sleep," I have been apprehensive of such extreme cases of apnea. Dr. Schreiber has proved that my apprehensions were justified because the remote consequences are found by the brain surgeon to be serious brain injury. When we do an operation in gynecology, we do not estimate our results by the patient getting off the table alive; we estimate our results by the remote consequences. Have we cured the patient of that for which we operated? In this late furor of painless childbirth, I have no intention of criticizing the relief of pain in labor; but this paper emphasizes that we must evaluate the individual to whom it is safe to give it, the individual to whom it is unsafe to give it, and the remote dangers of apnea following the use of any analgesic. I was impressed when I read the text of this full paper that the majority of all the author's cases in which considerable damage was done had one factor in common; that is, apnea at birth, 72 per cent of them. The 68 per cent who had no analgesia but had apnea also showed the same brain damage. Apnea is evidently a dangerous condition, perhaps more dangerous remotely than immediately. The table which showed the deliveries accomplished without any anesthetic or any analgesia showed only 2 per cent of apnea while with all the different analgesic drugs the cases of apnea ranged from 35 to 67 per cent. Therefore, on the average, when analgesics

are used, apnea occurs from seventeen to thirty-three times as often. If the author's thesis is correct, which I believe it is, it behooves us to reevaluate our attitude toward analgesics in labor with the remote as well as immediate results in mind. I feel convinced that he has established his thesis that the degeneration of the cerebral tissue is positively demonstrated and that analgesia beyond the same pharmacologic dose is a causative factor in the fetal anoxemia with the resultant cerebral damage. There are many lessons that can be learned from this paper. The one that has impressed me most is that the question of relieving the pain of labor must be reevaluated, the remote results and not only the apparent immediate results being kept in mind.

DR. CHARLES E. GALLOWAY, Evanston, Ill.: For about five years I have tried my best to look at this problem in a rational manner, because I feel that women in childbirth deserve to have as much of the pain relieved as possible with safety. But I think that physicians must be very careful in the use of analgesics in childbirth, because it is an added factor in fetal mortality. However, whenever one looks at any problem one must look at it as a whole and not from any one standpoint, and I think the pain of childbirth can be safely relieved, at least the intense suffering can be taken from the patient, without damage to the infant. When I heard about this paper I wrote a letter to every man who has taken care of any babies out of Evanston Hospital over the last five years and also to our leading neurologist in the community, who takes care of practically every case of infant mental deficiency. The letter in part was as follows: "In Detroit, and I presume other places in the country, men have been using large doses of scopolamine repeated as many as six times during labor, together with as much as 6 grains of pentobarbital. Consequently, they have had a high fetal mortality. But ever more important, they have found a small percentage of these babies mentally defective or at least constituting what might be called problem children. Those doses of $\frac{1}{100}$ grain of scopolamine repeated time after time is, I think, an abnormal medical procedure, and we at the Evanston Hospital have seldom ever given more than $\frac{1}{150}$ grain of scopolamine at any time, and it has been practically never repeated. We seldom give more than 6 grains of pentobarbital, and only occasionally does it run up to 9 or 10½ grains. Since the five and one-half years we have been using these drugs, they have been administered to only 60 per cent of the patients delivered, and there have been only two maternal deaths among the patients receiving the drugs. Please tell me what you think about the possibility of any mental damage in these babies. I expect to sum up the various answers and incorporate them in my discussion." I received about eleven answers out of thirteen letters, and the consensus among the men who have been treating such cases is that mental damage does not occur. Why the authors get so many cases in one community I cannot see, but I should like to make two statements. One is that such a procedure during labor, of giving repeated large doses of scopolamine, is very poor medical practice. The other is that I think these men have not entirely proved their thesis. I think that more work will have to be done and one will have to compare the incidence of mental damage in cyanotic babies with the incidence of mental damage without cyanosis at birth. Since the world began, about 2 per cent of the population has been born defective mentally and it may even be that a baby is cyanotic at birth because it is mentally deficient. I also believe that one expects a baby with cerebral hemorrhage to be unable to breathe.

Hippocrates' Clinical Records.—The writings of Hippocrates were copied and recopied for centuries, used by Galen, and, more or less garbled, studied almost up to the eighteenth century, when critics began to use them chiefly for historical material. Clinical records of forty-two cases have come down to us from Hippocrates, so clearly treated that Osler and Sydenham took them as model records. Among these cases were quinsy, diphtheria, typhoid fever, pleurisy, dislocations of bones, and injury to the skull.—Hurd-Mead, Kate Campbell: *A History of Women in Medicine*, Haddam, Conn., the Haddam Press, 1938.

PROCTOLOGIC TUMORS

C. C. TUCKER, M.D.

AND

C. A. HELLWIG, M.D.

WICHITA, KAN.

Most modern hospitals have accepted the principle of examining microscopically all tissue removed by operation. While gynecologists adhere to this rule regardless of the size of the specimen, most proctologists regard histologic study as unnecessary when small amounts of tissue are removed, especially when hemorrhoidectomy is performed.

During the last six years we have studied by microscopic methods every specimen removed during anorectal operation, no matter how small the lesion and how harmless its gross appearance. Reviewing our clinical and pathologic records of 951 proctologic patients, it is evident that in the majority of cases nothing has been detected by histologic study which changed the prognosis or treatment based on clinical examination. This, however, is true also in the fields of major surgery and gynecology. There are, on the

Fig. 1.—The intermediate zone of the anal canal is lined with epithelium resembling bladder papilloma. It is a remnant of the fetal cloaca. There were four papillary tumors in this area among our cases.

other hand, so many cases in our material in which the microscopic examination revealed conditions which were not suspected clinically that the routine histologic study of proctologic specimens seems well justified, in the interest of the patient.

McCarty,¹ basing his statistics on 150,000 surgical cases, found that routine microscopic examination revealed in 0.5 per cent of all operations a malignant condition which was not suspected by clinical methods or during operation. In our series of 951 proctologic cases this percentage of clinically unrecognized cancer is almost four times higher, namely 1.9 per cent. The conclusion therefore is justified that, more than in other regions, early malignant lesions of the anal canal may closely resemble harmless conditions.

There is considerable confusion in the literature regarding the anatomic limitations of the anal canal. We follow the definition of Rosser,² who regards as anal canal the lower portion of the rectum. It coincides with the pars perinealis of the anatomic nomen-

clature and extends from the perineal flexure of the rectum to the anus. It is narrowed by the sphincters and levators and is the site of anal disease. While the anal canal forms a physiologic and pathologic entity, histologically it is a complex structure. Its interior surface is lined with three different forms of epithelium which are of different fetal origin. The upper zone of the anal canal has typical intestinal epithelium with columnar cells and Lieberkühn glands. The middle or intermediate zone is a remnant of the fetal cloaca and is lined with transitional epithelium as found in the urinary bladder and urethra. This zone extends from the recto-anal line down to the anocutaneous or dentate line. The crypts of Morgagni and the anal ducts are the most important structures of this area. The distal portion of the anal canal is purely ectodermal and is called the cutaneous zone.³

Buie⁴ limits the term anal canal to only this portion which is lined with squamous epithelium. No glands are found in this zone. Sweat glands of large size, the so-called apocrine glands, sebaceous glands and hair follicles characterize the beginning of true skin or perianal region. The junction between the cutaneous zone of the anal canal and of the perianal region is called anus according to the anatomic nomenclature of Basel. To understand the great variety of anal tumors one has to keep in mind the three different types of epithelium lining the anal canal and its complex fetal development.

The uppermost zone of the anal canal is the favored site of glandular neoplasms. In our series there were fifteen adenomas and thirty-five adenocarcinomas. In the intermediate zone, which is more predisposed to inflammatory lesions than other parts of the anal canal, tumors are relatively rare. We found four benign papillary tumors resembling bladder papilloma, one melanoma and two adenocarcinomas in this area. Distal from the anocutaneous zone there were, in our series, four squamous cell carcinomas, one melanoma and one basal cell carcinoma.

Connective tissue tumors did not show predilection for different portions of the anal canal as did the epithelial growths. There were twelve benign and six malignant tumors. Besides lipomas, fibromas and myomas we found one hemangio-endothelioma, one myxoma, one xanthoma and one myosarcoma, one spindle cell sarcoma and two lymphosarcomas.

Many of the malignant tumors in our material were small and eighteen of the fifty-two malignant tumors were discovered during routine histologic examination of what seemed clinically harmless anal lesions. Two adenocarcinomas and the basal cell carcinoma were completely removed by hemorrhoidectomy and in the specimen removed at the subsequent radical operation after the histologic diagnosis was established no trace of malignant tissue could be detected.

In six of our fifty-two malignant cases, cancer developed in previously existing anal lesions. One adenocarcinoma was found originating in a fistulous tract, one squamous cell carcinoma in a fissure, three adenocarcinomas in hemorrhoid nodules and one basal cell carcinoma in an external hemorrhoid.

In 1931 Rosser² reported thirteen cases of anal malignant growths which had some benign pathologic condition as the etiologic agent and further reviewed an

additional eighteen cases from the literature which showed some anorectal disease as a forerunner. Of Rosser's thirteen cases, the etiologic factors in seven were fistula, in four hemorrhoids and in two cryptitis and papillitis. Buie and Brust⁵ in 1933 reported fifty-one cases of anal malignancy in which thirty-four showed some benign anal lesion as a forerunner. In 1937 T. E. Smith⁶ published the results of a review of the literature and personal correspondence with leading proctologists. In his report there are 107 cases of anal

Fig. 2.—The dark tumor at the right appeared clinically as a thrombosed hemorrhoid nodule. Microscopically it was a malignant melanoma.

malignancy developing from benign lesions. He does not include adenomatous polyps, which are generally recognized as precancerous conditions.

Our material of adenomatous polyps could be classified with one exception by histologic criteria as either benign or frankly malignant tumors. Only one polyp showed atypical glands in a small area, probably a transitional stage of a benign into a malignant growth. The fact that hypertrophic anal papillae are often confused with adenomatous polyps has been stressed in a recent paper by Tucker⁷ of San Antonio. In several cases the diagnosis of adenoma was made by an occasional proctoscopist, when the location in the dentate line and the whitish surface characterized these structures as enlarged papillae. We agree with Tucker⁷ that hypertrophic papillae do not carry a serious prognosis as compared with adenomas.

Not infrequently, patients seek proctologic advice while their symptoms are caused by extra-anal conditions. The complex embryologic changes occurring in the sacral region explain the origin of chordoma (two cases in our material), teratoma (one case) and dermoid cysts. Of pelvic tumors which produced symptoms calling for proctologic examination were one ovarian dermoid which became infected and perforated into the rectum, and one adenomyoma of the rectovaginal septum. A patient with a tumor of the cauda equina consulted first the proctologist on account of anal discomfort. Of interesting tumors in the perianal region we observed a sweat gland adenoma, a myxoma and a hemangioneuromyoma of the glomus type.

REPORT OF CASES

CASE 1.—History.—Mrs. H. J., a widow aged 64, admitted to St. Francis Hospital Jan. 15, 1931, had complained of hemorrhoids for the past thirty years. There was no history of bleeding but the patient complained of constipation and constant

pain in the back. On examination internal and external hemorrhoids were found. Operation was performed January 16 and tissue was sent to the laboratory.

Pathologic Examination.—There were five nodules of different size, the largest one 1 cm. in diameter, the smallest 4 mm. The surface of the nodules was folded and apparently not ulcerated. No suspicious changes were evident to the unaided eye.

Microscopic examination disclosed that the epithelium of four nodules was of typical appearance, representing either columnar or transitional epithelium. There were slight inflammatory changes in the subepithelial tissue, and large blood-filled spaces were found in the stroma. In one nodule which was taken from the junction between squamous and columnar epithelium there were glands of irregular structure. The lining cells were not well oriented and the nuclei were hyperchromatic. In a few glands several layers of epithelial cells were found. No basement membrane could be made out. These atypical cells had invaded the submucosa and had reached in one place even the muscular layer. Few of the alveoli were filled with mucoid material and exfoliated epithelial cells. No mitotic figures were found. The areas of atypical proliferation were surrounded by round cells.

The pathologic histologic diagnosis was adenocarcinoma at the junction of the squamous and columnar epithelium in one of five hemorrhoid nodules.

The patient was given high voltage roentgen therapy and radium. The radiologist reported that from January 26 to January 31 he administered 600 roentgens, using 15 and 20 cm. portals, a filter of 0.5 mm. of copper and 1 mm. of aluminum, 65 cm. tube distance, from 180 to 200 kilovolts, 8 milliamperes and twenty-five minute treatments. February 2 he administered 50 mg. of radium in a T applicator in the rectum for forty-eight hours. Feb. 18, April 8, Nov. 25, Nov. 28, Dec. 1, Dec. 8 and Dec. 19, 1931, and March 12, 1932, ultraviolet treatment was given. There has been no recurrence to date.

CASE 2.—History.—G. W., a white man aged 67, entered the proctologic department of the clinic Sept. 13, 1935, and on rectal examination a fistula in ano was found together with internal and external hemorrhoids and infected anal ducts. The patient complained of pruritus ani.

X-ray examination was negative. The patient stated that he had a chill about once a week. He had a severe chill about three months before, associated with gallbladder colic. X-ray

Fig. 3.—Hemangioma of anal canal. Clinical diagnosis, hemorrhoid.

examination showed nonvisualization of the gallbladder and no evidence of stone. The patient had chills and fever as a child when he came to Kansas. A malarial smear gave negative results. On the following day operation was performed at the County Hospital.

Pathologic Examination.—The solid nodule was composed of very atypical glands, which were invading the muscle layer. The epithelium lining the glands showed malignant characteristics. The cells were in several layers and poorly oriented. The nuclei were large and vesicular and had large nucleoli. The stroma was extremely scanty and showed round cell infiltration. In one section a hypertrophied papilla was found

with marked round cell infiltration of the subepithelial tissue. At the proximal base of the papilla, inflammatory changes were found near a duct.

The pathologic diagnosis was adenocarcinoma.

Six weeks later a perineal excision was performed. No evidence of cancer was obtained on microscopic examination. The patient has remained well to date.

CASE 3.—History.—R. C., a white man aged 43, a sales manager, first noticed bleeding from the rectum two years before. The bleeding was small in amount and occurred at irregular intervals. The bowel movements were regular. Pain began about the week previous to admittance to the hospital. Physical examination gave negative results. Proctoscopic examination revealed infected anal ducts, an enlarged papilla at the anorectal line anteriorly which resembled a tumor, and internal and external hemorrhoids. The patient was admitted to St. Francis Hospital Nov. 29, 1937, and operated on the following morning.

Pathologic Examination.—There were eleven specimens varying in size from 2 cm. to 5 mm. Three were covered with skin. Several had large blood vessels.

Microscopic examination revealed several large papillae with markedly hypertrophic epithelium and round cell infiltration. The epithelium showed parakeratosis. There were several ducts with definite inflammatory changes in the wall. The

Fig. 4.—Two fibromas and one lipoma in anal canal.

internal and external nodules had large blood vessels with thin walls. No inflammatory changes were found in the skin. In one hair follicle extensive proliferation was noticed. The cells were invading the surrounding tissue and there was formation of small cysts. The structure was that of early basal cell carcinoma.

The pathologic diagnosis was external and internal hemorrhoids and infected anal ducts, hypertrophic papillae and minute basal cell carcinoma.

The patient was given high voltage roentgen therapy and radium. Jan. 5 to Jan. 12, 1938, 3,414 roentgens was administered; 15 by 15 and 20 by 20 cm. portals were used with 1 mm. copper and 1 mm. aluminum filter, 50 and 60 cm. tube distance, 185 kilovolts and 8 milliamperes. January 22, 50 mg. of radium was administered in the rectum in a rectal applicator in two layers of rubber rotated 120 degrees every four hours for twelve hours, 12 by 50, or 600 milligram hours.

The patient will continue to be examined proctoscopically every two months. There has been no recurrence to date.

CASE 4.—History.—Mrs. L. J., aged 45, white, American, a housewife, for the past two years had had some pain in the rectum but no bleeding. Four years before she had a hysterectomy for uterine fibroids, which on microscopic examination showed no evidence of malignancy. She was admitted to the hospital in May 1937 for a rectal operation. A diagnosis was made of internal and external hemorrhoids, with a papilloma at the anorectal line. There were several internal hemorrhoids and thrombosis of external hemorrhoids.

Pathologic Examination.—The section showed well preserved surface epithelium consisting of squamous cells with some hornification of the superficial layer. In the subepithelial stroma cross sections of two anal ducts were found. They were lined

with transitional epithelium. The lower third of the section consisted of an atypical glandular growth. The tumor consisted of ducts which varied in size and form. There were many solid strands without lumens. The tumor cells were poorly differentiated. They were cuboid and varied in size and staining quality. Some mitotic figures were found. There was no evidence of secretory activity. The stroma between the ducts was extremely scanty. There were no inflammatory changes. The location of the glandular growth and the presence of two typical anal ducts suggested the origin of this adenocarcinoma in the anal ducts.

The pathologic diagnosis was adenocarcinoma of the anal canal originating in anal ducts.

SUMMARY

The clinical and histologic study of 951 proctologic cases emphasizes the wide range of pathologic possibilities causing anal symptoms and the close resemblance between harmless and the most malignant anal lesions. One third of our malignant lesions were discovered by routine histologic examination of clinically benign lesions. Rossers' theory that cancer may develop in long standing benign anal lesions was substantiated by six of our own cases.

A comparison of the clinical and pathologic diagnoses in our 951 cases proves the value of routine microscopic examination in proctologic practice.

ABSTRACT OF DISCUSSION

DR. CURTICE ROSSER, Dallas, Texas: Those who have attended the meetings of this section during the past five years will recognize that this is the third of a series of clinicopathologic papers presented by these authors, a valuable type of report in which the clinical observations of one author are synchronized with the gross and microscopic study of his confrère. In my work in the wards of Baylor University Hospital in Dallas for some years I have noticed this association of benign lesions in the anal canal. In a recent analysis of twenty-five cases of cancer of the anal canal I found that in 87 per cent of them there was an associated benign lesion. There are certain ex cathedra statements which get into the literature more or less casually, which are repeated and copied from one paper or textbook to another, until it would seem that it would require a charge of dynamite to extricate them. Such a statement was that of Paul Kraske, some fifty years ago, that he saw no particular evidence that benign lesions of the anal canal were etiologic agents in cancer. That statement, unsupported by any evidence, has been copied in at least a hundred papers. It crept into the first edition of a standard textbook on tumors, for example, and it has gone through four editions without any change in that textbook. This fact is the reason for presenting evidence that a benign growth in the anal canal may precede and in some way cause the following malignant lesion. As Drs. Tucker and Hellwig have shown, routine biopsy is absolutely essential in the surgery of all presumably benign lesions. Practically one third of their cases of malignancy were discovered in apparently benign lesions, and that, I believe, is sufficient warrant for our insistence on this particular premise.

DR. L. E. BROWN, Corona, Calif.: That all apparently benign lesions of the rectum and anus should be sectioned and studied under the microscope is shown clearly in two cases which I have had within the past year. Two children, one 18 months and the other 2 years of age, each had a polyp from 1.5 to 2 cm. in diameter. On removal and section, they showed adenocarcinoma grade I. In one of these, to date, the tumor has not returned. In the other one there is another tumor of about the same size that has developed on the opposite side of the rectum. If children 2 years of age or less have adenocarcinoma, certainly it behooves us to consider other tumors in older persons as precancerous tumors, and therefore they should be sectioned and studied.

DR. EDWARD G. MARTIN, Detroit: In discussing this paper, may I add a theory in which I thoroughly believe. One must

differentiate between so-called precipitating causes of cancer and the primary etiologic factor itself. In my opinion, cancer no matter where it is found is caused by an individual susceptibility to an unknown something which as yet remains undefined; something which permits the initiation of the malignant drive. If the use of the term is not too hackneyed, call it protracted allergy. This theory lends itself reasonably to any discussion bearing on the etiology of cancer. Injury is often considered an etiologic factor in cancer of the breast, yet there are probably a thousand injuries in which no cancer develops to each one that does; the individual susceptibility, in other words, is lacking. Consider cancer in any location and the current discussion of its cause; the same reasoning applies. If smoking a pipe caused cancer of the lip or tongue without an individual susceptibility, there would be a thousand times as many cases as there are. If anal disease, such as fistula and hemorrhoids, were an important factor in the etiology of cancer, anal cancer, which is comparatively rare, should be found daily. Such work as has been presented by the authors is of the utmost importance in forming a background for the study of cancer, and without such pioneer work little would be known about cancer. The observations which have been made disclose the desirability of caring for all anal disease and more careful examination leading to such care. Statistics do not prove that cancer is hereditary, and as a matter of fact the incidence of cancer, strangely enough, has been found to be greater in the family histories of those without cancer than it has among those patients who suffer from the disease.

OSTEOMAS OF PARANASAL SINUSES AND THE MASTOID PROCESS

REPORT OF CASES

BERT E. HEMPSTEAD, M.D.
ROCHESTER, MINN.

Osteomas that arise in the paranasal sinuses are not common. Occasionally they are discovered in routine roentgenologic examination of the sinuses. They are not diagnosed clinically or even suspected of being present until either evidence of intracranial complications becomes manifest or external deformities appear. From time to time, articles have appeared that contain reports of cases and give the number of cases previously reported. It is not the purpose of this paper to give a detailed review of the literature; rather, it is to stress methods of handling cases. In 1935 Dr. Carmody reviewed the cases reported up to that time.

ETIOLOGY

The etiology of these bony growths never has been determined. The ethmoid bone is developed from cartilage and the frontal bone is developed from membrane. Osteomas develop frequently at the site of the fronto-ethmoidal suture. Arnold¹ advanced the hypothesis that cartilaginous rests were present and that these enlarge and develop later into bone. He pointed out that where tissues of different embryologic origin come together there is a predisposition to growth of tumors.

Against this hypothesis is the fact that no cartilaginous debris ever has been found in these tumors and that tumors appear at sites where this difference in embryologic derivation does not exist, such as at the recessus nasalis of the frontal bone, at the maxillary antrum and at the tip of the mastoid bone. Virchow¹

believed that the site of origin of such tumors is the diploe of the frontal bone. Scarcely would this explain occurrence of the growth in other places. Infection has been suggested as a possible cause, but many times the tumor is present without any evidence of infection, either macroscopic or microscopic. A history of trauma is obtained many times. The blow, however, usually is so insignificant that probably it is not the etiologic factor. Bornhaupt¹ advanced the hypothesis that such tumors originate from the periosteum.

PATHOLOGY

These tumors may be hard and eburnated in structure, they may be spongy, or they may consist of a mixture of these two types of structure. Growth is very slow. Usually the tumor is attached by a pedicle of cancellous structure. This growth can prevent drainage of the sinus and thus can give rise to a pyocele or mucocele, which may be the direct cause of deformity.

Fig. 1 (case 1).—Osteoma in ethmoid region before operation.

DIAGNOSIS

The small osteoma which elicits no symptoms is discovered only in routine roentgenologic examination of the paranasal sinuses. This type of osteoma should be reexamined subsequently at periodic intervals and, if any evidence of growth appears, should be removed.

The patient who has an osteoma usually presents himself because of pain, external deformity or symptoms due to an intracranial complication. Roentgenologic examination is of the greatest service in indicating the exact site of the tumor and whether or not it has invaded the cranial cavity. This point must be determined carefully by stereoscopic examination, since the surgical approach depends much on this. Presence of pyocele or mucocele cannot be determined always preoperatively because the results of examination of the nose can be negative. If the nasofrontal duct is occluded, conditions are ideal for development of either pyocele or mucocele.

OPERATIVE REMOVAL

Cushing² in 1927 reported four cases in which osteoma of the fronto-ethmoidal region occurred, with

From the Section on Otolaryngology and Rhinology, the Mayo Clinic. Read before the Section on Laryngology, Otology and Rhinology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

1. Quoted by Armitage, George: Osteoma of the Frontal Sinus, with Particular Reference to Its Intracranial Complications and with the Report of a Case, *Brit. J. Surg.* 18:565-580 (April) 1931.

2. Cushing, Harvey: Experiences with Orbito-Ethmoidal Osteomata Having Intracranial Complications, *Surg., Gynec. & Obst.* 44:721-742 (June) 1927.

intracranial complications. Operation in all was performed by use of an osteoplastic flap which allowed exposure of the tumor from above. In each instance the osteoma had pushed the dura ahead of it and it was not possible to separate the dura from the tumor without producing a tear. Two of these patients died of meningitis. The other two patients were benefited by use of a fascial stamp taken from fascia lata and

Fig. 2 (case 1).—Osteoma removed from ethmoid.

placed over the tear in the dura. This prevented occurrence of cerebrospinal rhinorrhea with subsequent meningitis. Cushing called attention to the fact that removal of such osteomas is a serious operation and that the ophthalmologist, the neurosurgeon and the rhinologist should consult and decide on the best method of approach. He said that there could

be no more permanence to the boundaries of a surgical specialty than there could be to the boundaries of the Balkan states.

He is undoubtedly correct in stating that if a tear is likely to occur in the dura owing to separation of it from the tumor or if a tear already is evidenced by presence of pneumatocele or other intracranial complication, surgical approach should be from above. Harris³ and Carmody,⁴ however, reported cases of a like tumor associated with cerebral extension of the lesion; the tumor was removed successfully by use of the usual incision for the fronto-ethmoidal type of operation.

Presence of infection in the frontal or ethmoidal sinus makes the approach used by Cushing much more hazardous, as meningitis or infection and subsequent loss of the bone flap may occur. In view of the fact that most often an associated sinusitis is present, it seems to me that the usual fronto-ethmoidal approach will not only permit removal of the tumor but also assist adequate handling of the infection. If, in the course of operation, it becomes evident that there is danger of tearing the dura, operation can be stopped after thorough drainage has been established and after the sinusitis has been cared for; the tumor can be removed at some future time by the method used by Cushing.

Most osteomas are not associated with extension of the lesion to the cerebrum and can be removed through the fronto-ethmoidal incision.

CONCLUSIONS

1. Osteomas of the paranasal sinuses are not common.
2. Most osteomas can be removed through the fronto-ethmoidal incision.
3. If osteomas do not involve the dura or cribriform plate, removal by the method of Cushing is illogical.

3. Harris, Robin: Osteoma of the Frontal Sinus: Report of Two Cases, *Laryngoscope* 38: 331-346 (May) 1928.
4. Carmody, T. E.: Osteoma of the Nasal Accessory Sinuses, *Ann. Otol., Rhin. & Laryn.* 44: 626-643 (Sept.) 1935.

4. Pyocele or mucocele of the sinuses can be handled best through the fronto-ethmoidal incision.

5. Osteomas associated with intracranial complications are cared for best through the transfrontal approach.

6. If osteomas are associated with intracranial complications and with definite infection of the sinuses, operation might be done in two stages with advantage.

REPORT OF CASES

CASE 1.—A youth aged 17 years came to the clinic Jan. 7, 1935, complaining of bulging of the left eye, epiphora and pain in the orbit. Bulging had been noticed for three weeks, pain for about three months and epiphora for five months. There had been no intranasal symptoms. His general health had been good. Vision and visual fields of both eyes were normal. The left eye protruded downward and outward.

Röntgenologic examination gave evidence of the presence of a large tumor, apparently of bone, that filled the left ethmoidal region and protruded into the left orbit (fig. 1). The bony mass also could be palpated with a probe in the left middle meatus.

January 12, operation was performed under intratracheal anesthesia. The incision was made in the left brow and was extended down the side of the nose. The periosteum was retracted and the tumor was found presenting at the region of the inner canthus. The tumor was of such density that it could not be removed in pieces. The os planum and parts of the lacrimal, nasal and superior maxillary bones were removed. The osteoma was then grasped with a rongeur, was rocked from its bed and was delivered entire. The growth measured 4.5 by 4 by 2.5 cm. (fig. 2). The wound was closed. Convalescence was uneventful. The patient was dismissed on January 26, at which time the wound was healed. The diplopia,

Fig. 3 (case 1).—Appearance after removal of osteoma from ethmoidal region.

which had developed postoperatively, had disappeared and the eye was in its normal position, the exophthalmos having disappeared (fig. 3).

In case 2 a large osteoma was situated on the mastoid process. This is the only case ever seen at the clinic and I can find no similar case reported in the literature in English. Several cases, however, have been reported in the German literature.

CASE 2.—A woman aged 22 consulted us at the clinic on Feb. 27, 1928, because of pain behind the left ear. She gave

the history of discharge from this ear six years previously; the discharge ceased in a few days. The discharge did not recur but, four months before she came to the clinic, she had noticed a mass behind the left ear and some pain. Examination gave evidence of a normal membrana tympani and normal hearing. There was a hard, firm mass, about 2 cm. in diameter,

Fig. 4 (case 2).—Osteoma of mastoid before operation.

lying over the tip of the mastoid prominence. Roentgenologic examination gave evidence that this was an osteoma. Surgical removal was not advised (fig. 4).

The patient returned to the clinic May 6, 1929, and stated that she had experienced no trouble with the ear since her last visit. She again returned Jan. 7, 1935, because of abdominal pain. She was referred to the Section on Otolaryngology and it was noted that the tumor was enlarged markedly. Roentgenologic examination gave evidence that the mastoid cells were not involved. The patient was desirous of having this tumor removed because of its size.

Under general anesthesia the growth was removed and it was found attached to the tip of the mastoid. This attachment was cut through with a chisel and the growth, measuring 6.5 by 5 by 3.5 cm., was removed (fig. 5). The bone along the attachment was removed in order to prevent recurrence. The wound healed by primary union.

The pain complained of by this patient was not caused by the osteoma but by an unerupted wisdom tooth. This was removed.

ABSTRACT OF DISCUSSION

DR. GEORGE H. WILLCUTT, San Rafael, Calif.: The subject of osteoma of the paranasal sinuses is of interest because many of us who are not associated with the larger clinics and hospitals don't see many of these cases. In 1935 in Toronto Dr. Carmody reported a number of cases of osteoma of the frontal sinus and also included some of the antrum. Dr. Carmody had attacked those also by the direct method rather than by the upper or more complicated method of Dr. Cushing. Osteomas arising in this region are not common. In the last decade more cases have been reported, possibly because of more careful diagnosis. A differential diagnosis is sometimes difficult unless microscopic examination of the tissue removed is done. Most writers seem to agree that the etiology of these growths is debatable. Dr. Hempstead outlined well the various theories and hypotheses of Arnold and Bornhaupt and Virchow and others. The technic of Dr. Harvey Cushing, which he presented in 1927, was to attack these cases from above, making a big osteoplastic flap. He stressed the dangers and the seriousness of such a procedure and it rather discouraged the average operator from attacking the condition. Dr. Hempstead advances

the idea that a much more simple method is feasible. The osteoma isn't the bugbear that it appeared to be from Dr. Cushing's point of view. Naturally, if one should run into a case of extension into the cranial cavity, it might be more difficult to attack it by this method, but one could do the first step of the operation and then at a later date go in from above, or one could get somebody else to go in from above who was more familiar with that technic. It is a revelation to find that this tumor can be attacked by the average man without the necessity of becoming an intracranial surgeon. Dr. Hempstead's mastoid osteoma case is extremely interesting. I was unable to find any reference to a similar case in American or English literature.

DR. THOMAS E. CARMODY, Denver: I don't know anything about osteomas of the mastoid because I have never seen one, nor did I see anything in the literature about it. Osteomas, like other conditions, may come all at once. Of the four that I reported of the frontal sinus (I also reported two of the maxillary sinus at that time), two came within two weeks and the other two came within two years (all of them came within two years), so one might run across many of them in a short time or one may not see any for several years. I had seen only one before in twenty-five years of practice. Dr. Hempstead's idea of the technic of the operation is the same as mine. I do not think it necessary to make a great operation of this, even though the cranial cavity has been invaded. In two of my cases the cranial cavity had been invaded. In one it gave no symptoms. In the other it gave marked symptoms, because the patient had an aphasia and paralysis of the arm and leg on the right side. This cleared up after operation but the man had an epileptic attack. There is a possibility in opening through the nasofrontal duct, because it was also involved with the orbit and the ethmoid, that the entrance of air and water was possible. There is a possibility that there was some pressure on the brain or on the dura in this case. Another patient had epilepsy before the tumor was removed. There was only a slight opening in the posterior wall of the sinus in this case, and the epilepsy was not relieved by removal of the tumor. Since my report, I have found twenty-two cases in the literature—fourteen frontals, two ethmoids, five maxillaries, and one involving the maxillary and frontal sinuses. There are a great many of these cases seen that have not been reported.

Fig. 5 (case 2).—Osteoma removed from mastoid process.

DR. HARRINGTON B. GRAHAM, San Francisco: I had occasion recently to see a patient with an extremely large tumor involving both frontal sinuses. The interesting part of this case is that I saw him in 1931. Comparing his roentgenograms at that time with those of the present affords a definite idea of the rapidity of growth of one of these tumors. The lesion at that time appears to have been about one fifth the size of the present growth. The difficulty in operating in these cases has been described by the author. In my case only one thing could be done and that was to remove the anterior wall of the frontal sinus. This wall proved to be very thin and was easily dis-

posed of. The tumor was discrete but was so large that it compelled me to divide it into two parts by chiseling through the center. After one half of the tumor had been removed it was possible to elevate the other half without injuring the posterior wall of the sinus. There were three distinct tumors lying in the left orbit which were not connected with the mother growth and I find from the literature that this is not an unusual condition; these separate tumors seemingly have their own blood supply and are found frequently in the soft tissues. Since Dr. Carmody's work there have been a good many cases added to the literature, especially from Hungary, where considerable work has been done on the pathology.

PATHOLOGIC CHANGES IN AMBLYOPIA FOLLOWING TRYPARSAMIDE THERAPY

P. J. LEINFELDER, M.D.

IOWA CITY

The pentavalent arsenical atoxyl, introduced in 1902 by Blumenthal,¹ was first used in the treatment of protozoan diseases in 1905 by Thomas.² Since, as the name indicates, the drug was considered nontoxic, it was used extensively in the therapy of trypanosomiasis, pernicious anemia and psoriasis. After the identification of *Spirochaeta pallida*, the drug was almost immediately applied to the treatment of syphilis. Extensive use of atoxyl soon demonstrated various cases of toxicity. Progressive loss of vision occurred frequently (Bornemann,³ Igersheimer,⁴ Beck,⁵ Fehr⁶), and studies of the visual fields showed that the subjective blurring of vision was accompanied by peripheral contraction that progressed to complete blindness. Once visual symptoms occurred, visual loss continued in spite of withdrawal of the drug. Loss of vision developed in nonsyphilitic as well as syphilitic patients, and it appeared that the drug acted specifically on the visual sensory mechanism.

In 1907 Ehrlich's⁷ studies in chemotherapy led to the discovery of arsacetin, a less toxic substitution product of atoxyl. The new drug was used only a short time, since clinical experience demonstrated that it also had a deleterious effect on vision (Sattler,⁸ Hammes,⁹ Iversen,¹⁰ Ruete¹¹). The hope for a non-toxic pentavalent arsenical led to the introduction of tryparsamide by Lorenz and Loevenhardt.¹² Once more clinical application showed that the new drug, although less toxic than atoxyl or arsacetin, also caused

deterioration of vision and optic atrophy (Woods and Moore,¹³ Neff,¹⁴ Cady and Alvis,¹⁵ Fine and Barkan,¹⁶ Mayer¹⁷). With tryparsamide, however, visual injury was less common, and improvement or at least a cessation of the toxic process occurred when administration of the drug was discontinued. Recent reports have adequately reviewed the clinical use and toxicity of tryparsamide.

Although the toxicity of the pentavalent arsenicals has been investigated by a number of authors, no satisfactory explanation for the visual pathologic changes has been determined. The toxic action of atoxyl, arsacetin and tryparsamide appears to have a special affinity for the visual system, for general symptoms most frequently do not accompany the ocular manifestations. Young and Loevenhardt,¹⁸ after experimental comparison, concluded that the aniline group in the ortho position contribute to the toxic effects of these compounds and that the pentavalent arsenic is only a secondary consideration. An indication that the visual loss is not due to arsenic or the aniline molecule of the drugs is that these substances when toxic to the visual system ordinarily cause a defect in the central field, while atoxyl and tryparsamide almost invariably cause concentric contraction of the visual fields. Furthermore, the disintegration of pentavalent arseni-

Fig. 1.—Visual fields taken prior to injection of tryparsamide; 2/1,200 tangent screen.

cals in the blood stream is very slow. From a quantity of the drug injected, arsenic is gradually split off; some of the drug remains (Igersheimer and Rothman¹⁹) in the blood and tissues, while a large portion is excreted unchanged in the urine. Young and Muehlenberger²⁰ considered the possibility of accumulation of tryparsamide as the cause of toxic effects. Igersheimer⁴ expressed the opinion that atoxyl itself or a reduction product of it acts directly on the cell. He stated also that the eye has a high affinity for the atoxyl molecule but not for arsenic. According to Meyer and Gottlieb²¹ arsenic can be demonstrated in animal eyes after poisoning with atoxyl but it cannot be identified after poisoning with arsenic. In their experiments the arsenic poisoning did not cause blindness. Osborne²²

showed that arsenic in moderate amounts can be identified in the rabbit brain after therapeutic doses of tryparsamide.

Although numerous cases of tryparsamide amblyopia have been observed clinically there have appeared no reports of histologic examination of the eyes and optic pathways in such cases. Reports of pathologic changes in amblyopia following the use of atoxyl were made by Nonne²³ and Birch-Hirschfeld²⁴ and following the use of arsacetin by Sattler.⁸ Nonne observed atrophy in the optic nerves, chiasma and tracts obtained from a patient who died several weeks after blindness occurred. A clinical recognition of optic atrophy had been made before death. In Birch-Hirschfeld's case a complete examination was made of a man who died two years after the beginning of administration of atoxyl and twenty-two months after complete loss of vision. The atoxyl was used in the treatment of psoriasis. His study disclosed degeneration of the third neuron, chromatolysis, disintegration of the retinal ganglion cells and gliosis of the retina. Some nuclei of the inner nuclear layer appeared faded. The peripheral portion of the outer nuclear layer contained many shrunken nuclei. There was almost total degeneration of the optic nerves but no evidence of inflammation. The ganglion cells of the lateral geniculate bodies also showed degeneration. After injection of atoxyl in experimental animals Birch-Hirschfeld²⁴ was able to demonstrate a similar condition. Changes in retinal ganglion cells were observed in the cat, and extensive chromatolysis was observed as early as nine and one-half days after injection in a dog. In some dogs he observed changes in the occipital cortex and geniculate bodies. He said that the retina was most susceptible to the poison but that the condition behaved like a purely degenerative process of the medullary sheaths of the optic nerves. Sattler described the pathologic changes in a case of amblyopia following treatment of pernicious anemia with arsacetin. Loss of vision began six weeks after the beginning of treatment and progressed to total blindness in an additional six weeks. Death occurred five weeks later. There were no demonstrable changes in the first neuron, but a shrinkage or a swelling of a few cells in the inner nuclear layer was seen. The greatest damage was to the retinal ganglion cell layer and the optic nerve. Gliosis and reduction in the number of the ganglion cells were reported. The ganglion cell nuclei were shrunken or had lost their sharp margins, and the Nissl substance was not visible. The greatest degree of myelin disintegration occurred in the anterior portion of the optic pathway. More recently Sattler²⁵ expressed the opinion that although one would expect the process to be primary in the retina it is possible that the processes in the nerve fiber and the retina advance at the same time. A striking fact concerning all the reports of pathologic changes is the absence of evidence of tissue changes outside the eye and the optic pathways, for the remainder of the organs and the central nervous system show no evidence of a related pathologic process.

These observations of the pathologic changes in amblyopia occurring after the administration of compounds containing pentavalent arsenic were made at a time remote from the onset of blindness. A complete study of a case in which pathologic material was

obtained nine days after the administration of 1 Gm. of tryparsamide and seven days after the onset of visual disturbances is presented:

A white man aged 52 was admitted Aug. 13, 1937, because of inability to walk. This manifestation, together with difficulty in control of the bladder, had begun two years previously. There was a history of gonorrhea in 1907. The examination showed 6/6 vision in each eye. The pupils were round and equal and reacted promptly and effectively in near accommodation, but the reaction to light was sluggish. Ophthalmoscopic examination revealed early optic atrophy of the primary type on both sides; the visual fields (fig. 1) showed contraction with a 2/1,200 mm. target on the tangent screen. The blood pressure was 140 systolic and 86 diastolic, there was a cord bladder, the patient was unable to walk and the Wassermann reactions of the spinal fluid and blood were 4 plus.

On August 16, 1 Gm. of tryparsamide was administered intravenously. On the morning of August 18 a cystoscopic examination was made and was followed by chills, vomiting and fever, the temperature reaching 103 F. During the afternoon of that day the patient complained of blurring of vision. The following morning there was no subjective central or peripheral vision, but the pupils responded sluggishly to light, as at the time of admission. The ophthalmoscope revealed no

Fig. 2.—Optic nerve. Old peripheral degeneration is evident; Held stain.

change in the appearance of the nerve heads or fundi. On August 20 blindness persisted, but no pupillary response to light could be elicited. The pupils were smaller than at previous examinations. The general condition of the patient failed progressively. Further external examination of the eyes disclosed no pupillary light reaction, and no new changes developed in the fundus. The urea nitrogen content rose to 130.9 with a creatinine content of 11.5, and death from uremia occurred on the morning of August 25. A complete necropsy was begun two hours after death.

General pathologic examination was made by Dr. H. P. Smith, head of the department of pathology. He reported that the liver showed no evidence of necrosis. The cells in the central part of each lobule showed fat droplets and fine brown pigment granules. The kidneys were markedly reduced in size (weighing 90 Gm. each), but the renal pelvises were distended. Histologically there were extreme changes of a chronic nature that had destroyed the tubules and hyalinized the glomeruli. The stroma between the tubules was involved in an extensive chronic inflammatory process. Although the pathologic changes were compatible with those of chronic nephritis, the inflammation and dilatation of the renal pelvis indicated the presence of pyelonephritis. There was no evidence of acute change. The pathologist believed that the patient had been on the verge of uremia for some time and that very little additional injury was necessary to bring about a critical change. Additional postmortem diagnoses were bronchopneumonia and meningovascular syphilis.

The posterior segment of each eye was fixed in absolute alcohol and acetic acid according to Nissl's technic for study of the retinal ganglion cells. Pieces of the nerves and tracts were fixed in osmic acid, Marchi, and solution of formaldehyde for hematoxylin and eosin, silver, and Held stains. Portions of the occipital cortex and the lateral geniculate bodies were placed in 10 per cent solution of formaldehyde in preparation for hematoxylin and eosin, and Nissl stains.

Fig. 3.—High power view of normal medullary sheaths of optic nerve; osmic acid stain.

The occipital cortex and the lateral geniculate bodies showed no evidence of injury to the cell bodies, and the topography of the regions was normal. There was neither chromatolysis nor disturbance of the nuclei. Fatty granules were observed in the cytoplasm of the cells of the lateral geniculate body and other regions, but these changes are considered physiologic in a person of this age.

The optic tracts posteriorly showed little evidence of change with the Held stain. Small areas of gliosis indicated the presence of an old atrophic process, but the osmic acid and Marchi preparations revealed no evidence of acute demyelinating disease. In the anterior portion of the optic tracts the changes were similar but the amount of gliosis was more definite. Staining of the axis cylinders with silver proved them to be intact.

The periphery of both optic nerves showed gliosis and old disintegration of the myelin sheaths that appeared in proportion to the visual field changes (fig. 2). No areas of inflammatory reaction were observed, and the nerve sheaths were of normal appearance. Osmic acid (fig. 3) and Marchi preparations showed no evidence of acute degeneration in the optic nerves.

Within the retina there was gliosis in the nerve head and retina consistent with the antemortem diagnosis of early optic atrophy. Low power microscopic examination of the retina showed a normal morphologic appearance, with the several layers distinctly discernible. Ganglion cells were present in abundance. Examination with the high power objective disclosed the rods and cones in a good state of preservation. The rod and cone nuclei appeared entirely normal. In the posterior segment of the eye the cells of the inner nuclear layer were for the most part normal, but in places cells of the innermost row appeared faded and almost homogeneous (fig. 4). The general nuclear morphologic appearance could be made out, but no evidence of a chromatin network or of cytoplasmic structure could be recognized. The appearance was that of ghost cells. In the central region of the globe these cells were occasionally seen, but as one passed toward the periphery their occurrence was more frequent. The ganglion cells were numerous, but the morphologic appearance was profoundly changed (fig. 5). The cells were irregular in outline, and the cytoplasm in some cells was cloudy while in others it had a foamy appearance. In most of the ganglion cells the Nissl substance had entirely disappeared, but a peripheral rim of Nissl granules was recognized in a few cells. The ganglion cell nuclei were variable. Some were large, homogeneous and apparently

swollen, while in some cells a faint indication of a chromatin net remained, and a few cells contained a nucleolus. Many glial cells were present in the ganglion cell and nerve fiber layers. The nuclear changes and the loss of Nissl substance indicate a profound cellular reaction similar to that seen in the central nervous system after acute intoxications.

COMMENT

The reports of pathologic changes occurring after the use of atoxyl (Birch-Hirschfeld) and arsacetin (Sattler) show several results similar to those here reported for tryparsamide. Both observers recognized changes in the ganglion cells and in the inner nuclear layer of the retina as well as degeneration of the nerve fibers of the optic nerve. In experimental work, however, Igersheimer was unable to find any evidence of change in the ganglion cells of the retina of the cat or dog, but Birch-Hirschfeld's animals showed abnormalities similar to those observed in his reported case. The pathologic state in the cases recorded differs from that in the present case, since in the previous cases the process had gone on to a chronic stage. Histologic examination immediately after administration of the pentavalent arsenicals and the development of amblyopia has not previously been reported.

The present study presents observations in agreement with previous reports in regard to the changes in the ganglion cells and in the inner nuclear layer, but evidence of acute primary degeneration of nerve fiber in the optic pathways was not present. It seems apparent that changes in the optic nerves, tracts and lateral geniculate bodies must be of a secondary nature; no evidence of acute change could be observed in these situations nine days after the administration of the drug, yet definite evidence of cellular change was observed in the ganglion cells of the retina. It seems probable that the amblyopia following the administration of tryparsamide, similar to that due to tobacco and

Fig. 4.—Peripheral part of retina. Two "ghost" cells are seen in the inner nuclear layer; Nissl stain.

alcohol, is caused by a primary degeneration of the ganglion cells of the retina and that there ensues a secondary degeneration of the nerve fibers and myelin sheaths. The significance of the changes in the inner nuclear layer is not known. It is possible that in less extensive injury these cells are most affected, and their degeneration results in the peripheral contraction of the visual field.

Birch-Hirschfeld expressed the opinion that arteriosclerosis or alcoholism might play a part in the causation of the condition. In this case neither of these con-

ditions was present. Accumulation of the drug has been held responsible for the pathologic changes, yet this patient received a single injection. Previous experience with tryparsamide amblyopia has demonstrated that, if ocular complications are to develop, evidence of the change usually occurs early in the treatment. In one of Birch-Hirschfeld's experimental animals extensive chromatolysis was observed nine and one-half days after the beginning of treatment, and the author ventured the opinion that the animal was idiosyncratic to the drug. Lillie²⁶ suggested an idiosyncrasy as the underlying cause of the amblyopia. The fact that the patient reported had extensive changes after a single injection of 1 Gm. of tryparsamide lends credence to this view.

SUMMARY

1. Acute degeneration of the retinal ganglion cells was observed nine days after injection of 1 Gm. of tryparsamide and seven days after the onset of blindness.
2. Acute degeneration of cells in the innermost portion of the inner nuclear layer was present.
3. Evidence of acute primary degeneration in the optic nerves and tracts was not present.
4. General pathologic changes due to arsenic poisoning were not observed.

ABSTRACT OF DISCUSSION

DR. FREDERICK C. CORDES, San Francisco: Dr. Leinfelder's report is the first histologic study of tryparsamide amblyopia. Certain observations were rather striking. The changes in the ganglion cells and innermost layers of the inner nuclear layer were very definite, especially in the periphery of the retina. The fact that the neuro-epithelial layer was not involved was also noteworthy. Of particular interest was the fact that examination of the occipital cortex, lateral geniculate bodies, optic tracts and nerves failed to reveal any evidence of acute inflammation or degeneration. The changes present in the optic nerve were those of an old process, easily accounted for by the preexisting optic atrophy. The changes noted in the retina have been observed in acute poisoning from methyl alcohol, ethyl alcohol, quinine, nicotine and atoxyl. Lillie and others have contended that the occasional cases of tryparsamide amblyopia reported have been primarily the result of idiosyncrasy to the drug. The fact that 1 Gm. of the drug produced such marked changes would tend to confirm this opinion. Clinical observation has shown that, aside from the subjective symptoms, the earliest changes are those of contracted field and not visible changes in the optic disk. The fact that the greatest changes were found in the periphery of the retina and that no acute changes were found in the optic nerve emphasizes the importance of careful field studies early in the course of therapy. The greatest controversy in tryparsamide therapy has centered around its use in the presence of optic atrophy. Last year Dr. Mayer presented a paper before this section on tryparsamide therapy which bore out his contention that tryparsamide was not contraindicated in optic atrophy. Dr. Leinfelder's report seems to confirm this. If the effect of tryparsamide in a sensitive person was primarily on the optic nerve and tracts, one would expect to find signs of acute degeneration or inflammation in these structures, especially in view of the fact that the eye was examined so soon after administration of the drug. Lorenz and Loevenhardt, in introducing the drug, warned against its use "in cases showing degenerative changes in the retina." The fact that the acute changes in the histologic report presented were limited to the retina should make us extremely cautious in advising the use of the drug in the presence of pathologic changes in the retina. Dr. Leinfelder's paper is an important contribution to the subject of tryparsamide therapy.

DR. MAX FINE, San Francisco: It is unfortunate that the picture was somewhat confused by the presence of an early optic atrophy in Dr. Leinfelder's patient. There is general agreement, however, that tabetic optic atrophy begins in the intracranial portions of the optic nerve. The absence of extensive atrophy in the optic nerves in the presence of marked degenerative changes in the ganglion cell and inner nuclear layers suggests that the process involved is one other than tabetic optic atrophy. A striking feature of the sections Dr. Leinfelder has exhibited is the relative integrity of the central portion of the retina and the progressively severe changes as the periphery is approached. These observations correspond in a rough manner to the peripheral constriction of the visual field in cases of tryparsamide amblyopia. The delayed appearance of optic atrophy in tryparsamide amblyopia, even when the field changes are severe, fits in with Dr. Leinfelder's conclusion that the degeneration occurs first in the inner nuclear layer. The ocular complications from tryparsamide may be divided for clinical purposes into two groups: One shows the usual reaction consisting of preliminary symptoms of blurring, followed by a depression of the peripheral field with relative sparing of the temporal field. The process is reversible if tryparsamide is discontinued early, when the field changes are not too far advanced. The second type of reaction, of more infrequent occurrence, is an acute intoxication in which the patient may go to complete blindness within forty-eight hours

Fig. 5.—Normal retina and ganglion cells are shown on the left. Acute degeneration of ganglion cells of the retina after injection of tryparsamide is seen on the right; Nissl stain.

after a single injection of tryparsamide. This reaction is much less reversible. There may be a degree of recovery, but usually there is severe permanent damage. I have seen three such patients who became almost totally blind after the first or second injection of tryparsamide. Each of these patients had an early primary optic atrophy before the institution of tryparsamide therapy. Dr. Leinfelder's case appears to fall into this group. The occurrence of more than 90 per cent of reactions with the first five injections speaks against a cumulative effect in the ordinary sense. Young and Meuhlenberger have shown through studies of urinary arsenic that whereas a great majority of persons excrete 95 per cent of the arsenic within twenty-four hours, a small number excrete the drug much more slowly, and in one instance arsenic was recovered from the urine after three weeks.

DR. JOHN E. WEEKS, Portland, Ore.: I have been interested in this subject because I have seen two cases of amblyopia from the use of tryparsamide. In neither was there any intimation of impairment of vision before the tryparsamide was administered. Both were cases of syphilis of long standing. In the first case three doses were given at five day intervals; the first two were small, the third a dose of 1.5 Gm. The vision on the second day after the last dose was impaired. The fundi showed almost no change. Vision of one eye was reduced to 22/100, of the other eye to 20/70. The fields of vision were narrowed concentrically in both eyes, about 15 degrees in one eye and 25 degrees in the other. The blood vessels were somewhat reduced in size. There was no exuda-

26. Lillie, W. I.: Peculiar Contraction of the Normal Fields Associated with Syphilis of the Cerebral Nervous System, Tr. Am. Ophth. Soc. 32: 153-163, 1934.

tion and no hemorrhage, but the temporal portions of the disks were a bit pale. Vision of 20/20 was recovered in both eyes, but moderate concentric limitation of the fields persisted. In the second case, tryparsamide had also been injected once before the second dose, from which the amblyopia followed, was given. The second dose was 1.5 Gm. given intravenously. The patient became totally blind in twenty-four hours. An ophthalmologist who examined him could not detect that he had any vision whatever. The fundi in this case were similar to the fundi in the other case. I saw the patient in the afternoon of the day of his complete blindness, at which time the right iris reacted slightly to the stimulus of light but not the left. However, within a week the vision was greatly improved and the field of vision was very much contracted. Eventually the patient obtained a field of vision of only about 20 degrees in each eye but a visual acuity of 20/20. I regard the use of tryparsamide as something that should be undertaken only after careful tests regarding the susceptibility of the patient to tryparsamide have been made. There is a widespread opinion that, wherever there is any atrophy of the optic nerve or any disturbance of the fundus from syphilis, tryparsamide should not be employed. This amblyopia corresponds to some extent to that of quinine amblyopia, but the use of tryparsamide has caused permanent total blindness in a few cases. No case of complete permanent blindness from quinine is on record.

DR. OTIS A. SHARPE, San Francisco: A man aged 25 was being treated for syphilis with tryparsamide. He was referred to me one morning for visual fields. He complained of some indefinite disturbance in the fields. I took the fields, and there was about 10 or 15 degrees concentric contraction. The vision was 20/15 in each eye. I advised discontinuance of the treatment. The next morning I was called to the ward, where it was reported that he had gone completely blind. When I first examined the background there was no visible change. The next morning, which was less than twenty-four hours, the man was completely blind; there were no changes in the backgrounds to be seen. There was a very slight reaction of the pupils to light. Five years later this man appeared in my office and wanted a report from me. I examined his eyes and the background showed perfectly white disks. He took the case to court, claiming that the tryparsamide was the cause of his blindness. The other side claimed it was syphilitic optic atrophy. I reported this because of the short time in which complete blindness developed.

DR. FREDERICK H. VERHOEFF, Boston: At the present time it seems to me to be of no practical importance whether tryparsamide or other arsenicals in producing blindness affect primarily the optic nerve or the retinal ganglion cells, but of course the question is of great scientific interest and may become of practical importance. I haven't the slightest doubt that Dr. Leinfelder has shown in this case that the ganglion cells were markedly affected, but I do not feel sure that they were primarily affected. It seems to me, in spite of the fact that histologically there was no evidence that the nerve fibers were affected, that it was perfectly possible that they may have been affected to such an extent as to produce changes in the ganglion cells. This question has arisen in connection with many toxic agents and in my opinion has seldom if ever been satisfactorily answered.

DR. EDWARD JACKSON, Denver: Bearing on the point that has been brought up by Dr. Verhoeff, many years ago I was consulted by a young man with very marked macular changes. There were some slight hemorrhages and a good deal of haziness in the macula. One of the first questions I asked him was whether there was any history of blindness or partial blindness in his family. He stated that absolutely there had been none; but two years after that Dr. George M. Gould, who knew the family, reported it as a case of Leber's disease, which without any doubt it was. I saw it at a very early stage, and the appearance of the retina seemed to point out what one would expect, that the nutrition of the ganglion cells in the macula was affected before the nerve fibers proceeding from that cell showed any sign of change. There was no sign at first of disease in the optic disks. It ran the course of Leber's disease.

DR. P. J. LEINFELDER, Iowa City: Dr. Verhoeff's question concerning whether the ganglion cells were primarily affected or the nerve fibers I think can be definitely answered. Although neurohistologic technic is by no means infallible, research that I have done with the optic nerve has shown conclusively that, if one sections or injures the optic nerve, pathologic changes are observable with the osmic acid and the Marchi methods as early as three days following the injury. Furthermore, the neurofibrils show disintegration within ten days. I think it is striking that in this case there were absolutely no evidences of acute degeneration in the nerve fiber of the optic nerve even close to the eyeball. Dr. Sharpe mentioned pupillary reactions. It is conspicuous in the literature that pupillary reactions are at first retained in spite of the subjective blindness. Dr. Weeks brings up two questions. One is whether the fundus was changed. I did not mention it in my primary discussion but, throughout the nine days following the injection of the tryparsamide, no changes in the fundus over those that were first observed were noted. There was no change whatever from the optic atrophy. As for patients who recover their vision, it is astounding to note the amount of reversible change that can occur in the ganglion cells of the retina following injury to the optic nerve or tracts. Extensive chromatolysis of the ganglion cells in the retina occurs early, yet a large percentage of these cells recover at a later date. This was demonstrated by Birch-Hirschfeld in 1900. Dr. Fine inquires concerning histologic differences between the nasal and temporal segments of the retina. I would not attempt an evaluation of such a thing on the histologic material available for one would need to make a great many calculations that would not yield any definite, usable data.

THE GORDON TEST FOR HODGKIN'S DISEASE

A REACTION TO EOSINOPHILS

JAMES B. McNAUGHT, M.D.

SAN FRANCISCO

In 1932 Gordon¹ reported that intracerebral inoculation of rabbits and guinea pigs with suspensions of lymph nodes from patients with Hodgkin's disease was followed in several days by an encephalitic syndrome of characteristic pattern. This was typified by early muscular rigidity, progressive incoordination, ataxia and spastic paralysis of the hind limbs, accompanied by loss of weight and subnormal temperature. Tissue suspensions from patients with acute Hodgkin's disease often produced in addition to these changes retraction of the head, opisthotonos and convulsive seizures, and the animals frequently died within a few days to a month. In the less severe type of reaction the animals passed into a chronic state with marked muscular atrophy and wasting. Gordon obtained these reactions with suspensions from nineteen of twenty patients with Hodgkin's disease and with none of forty-one control suspensions. He concluded from his studies of the properties of the pathogenic agent that it was undoubtedly a virus and was the primary causative agent of Hodgkin's disease. He proposed the biologic test as a specific one for the practical diagnosis of Hodgkin's disease.

From the Department of Pathology, Stanford University School of Medicine.

The Gordon test has been applied in 179 cases of Hodgkin's disease by various investigators² and found positive in 124 (69.3 per cent). In 210 of 214 control experiments (98.1 per cent), with suspensions of lymph nodes from normal patients and from patients with hyperplasia, adenitis, leukemia, tuberculosis, carcinoma and sarcoma, the test was negative. These results indicate that while the Gordon test is only 70 per cent accurate in detecting Hodgkin's disease it apparently is highly specific in distinguishing this condition from other dyscrasias of the lymph nodes.

Gordon³ persists in his belief that the causal agent of Hodgkin's disease is elementary virus bodies, and he has recently employed emulsions of his sensitized elementary bodies, recovered from the lymph nodes of patients with active Hodgkin's disease, in treating this condition. Warner⁴ reported beneficial results following the use of Gordon's sensitized emulsions in cases of early Hodgkin's disease. Other investigators⁵ have been dubious of the virus nature of the active agent in the Gordon test. They have based their skepticism on the observation that although the pathogenic agent is definitely filter passing and the disease produced in animals bears some of the characteristics of an infectious process the agent has not been cultivated in vitro nor has its passage from animal to animal been accomplished. Gordon reported that rabbits recovering from an initial paralysis were immune to a second inoculation of active material, but other investigators⁶ found such rabbits just as susceptible as the control animals.

Friedemann and Elkeles⁷ reported that intracerebral inoculation of rabbits with extracts of normal and pathologic human bone marrow, spleen and leukocytes produced a paralysis indistinguishable from that caused by the agent which Gordon discovered in glands from

patients with Hodgkin's disease. They expressed the opinion that their active agent could not possibly be a living virus since it withstood extracting treatment which no living virus or bacteria could be expected to tolerate. In support of this theory Kelser and King⁸ submitted tissues containing known neurotropic viruses of St. Louis encephalitis, equine encephalomyelitis and rabies to the extraction processes used on the leukocytic material, and in all instances the viruses were rendered inert. Friedemann suggested that the encephalitogenic agent of Hodgkin's disease and that in the spleen, bone marrow and leukocytes are of the nature of a proteolytic enzyme such as that demonstrated by Jochmann and Lockemann⁹ in 1908. The active agent was not found in all bone marrows or all specimens of pus.⁹ MacKenzie and Van Rooyen¹⁰ confirmed much of the work of Friedemann but found no relation between the proteolytic activity and the

Fig. 1.—The inoculation area in the cerebral cortex of a paralyzed rabbit (slightly reduced from a photomicrograph with a magnification of 160 diameters).

encephalitogenic property of the agent and thus did not identify it with Jockmann's proteolytic enzyme.

It is obvious that, in some marrow, leukocytes, pus and spleens as well as some lymph nodes from patients with Hodgkin's disease there is an active substance capable of producing a characteristic paralysis in certain experimental animals. Turner, Jackson and Parker²¹ recently published convincing evidence showing that the active agents of Gordon and of Friedemann are derived from the eosinophil and consequently are most probably identical. This evidence is in accord with my observations on the Gordon test, covering a period of several years, herewith presented.

METHODS

The procedures of Gordon¹¹ have been followed in the performance of the tests. With sterile technic, human lymph nodes obtained either at biopsy or at

autopsy were dissected as free as possible from fat and fibrous tissue, and a slice was removed for histologic examination. The remainder was weighed, minced with scissors, ground in a mortar and made into a 10 per cent suspension by the addition of beef infusion broth at a p_H of 7.2. The emulsions in cotton-stoppered test tubes were immediately cultured and then placed in a refrigerator for at least one week and often for two weeks or longer. If the cultures showed growth the emulsions were sterilized with phenol in concentrations as high as 0.5 per cent. When the glandular material was adequate a portion was ground, rapidly dried in a desiccator, transferred to a glass tube, sealed and stored in the refrigerator. After being autolyzed in the refrigerator the original emulsions were centrifuged, and 0.4 cc. of the clear supernatant fluid was injected into the occipital lobe of the brains of rabbits and a similar amount given intravenously through an ear vessel. The animals were observed daily for neurologic manifestations and records kept as to weight and temperature for at least thirty days and often for several months. Occasionally there were immediate paralysis and convulsions after the injection, but the animals so affected were not included in this series unless they appeared entirely normal within a few hours. In positive tests the animals had the rigidity, ataxia and paralysis described by Gordon after an incubation period of from three to fourteen days.

RESULTS

Lymph nodes from fifty patients were tested, some 200 rabbits being used. The nodes were obtained from thirty-seven by biopsy and from thirteen at autopsy. Many of the patients presented some clinical symptoms compatible with the diagnosis of Hodgkin's disease, and all had lymphadenopathy. In thirteen cases the diagnosis of Hodgkin's disease was made by histologic examination, while in the remainder it was based on a variety of pathologic conditions, as listed in the accompanying table, and the latter cases served as controls. The Gordon test was positive in ten of the thirteen cases of Hodgkin's disease (77 per cent) and was negative in three cases. The test was negative in thirty-five of the thirty-seven control cases (95 per cent).

The two control cases in which the Gordon test was positive are worthy of comment:

CASE 1.—A youth aged 18 had mild fever, a palpable spleen, generalized mild lymphadenopathy, clubbed fingers and bilateral bronchiectasis, with copious sputum containing *Streptococcus viridans* (alpha) and a partially hemolytic streptococcus (alpha prime). There were moderate secondary anemia and a leukocyte count of 10,000, with 43 per cent eosinophils. Careful investigation failed to reveal a satisfactory explanation for the eosinophilia. An inguinal and an epitrochlear lymph node were removed for histologic examination and the Gordon test. Both nodes yielded pure cultures of *Streptococcus viridans*. The sections showed chronic hyperplastic lymphadenitis with numerous eosinophils. The Gordon tests were positive. The status of the patient was followed for sixteen months, at the end of which he felt well and had gained considerable weight. The spleen was not palpable, and the superficial lymph nodes were smaller. He raised considerable sputum.

CASE 2.—A man aged 42, who felt perfectly well except for "swellings" on both sides of his neck, was seen at physical examination to be entirely normal except for a chain of hard discrete nodules on both sides of the neck, extending from behind the ears to the supraclavicular regions, and similar nodes in the left axilla and groin. The leukocyte count was 10,300, with 72 per cent polymorphonuclears and 2 per cent eosinophils. Biopsy of a cervical node revealed that a large portion of the lymphoid tissue was replaced by a squamous type of

epithelium with active mitosis. The remaining lymphoid structure was normal except for myriads of eosinophils. A careful clinical and roentgenologic search revealed no primary source for this carcinoma. Gordon tests were positive on the third day in the two rabbits inoculated. Subsequently an axillary node was removed; it was largely replaced by epithelial growth but contained only occasional eosinophils. Unfortunately this biopsy specimen came to me in solution of formaldehyde and a Gordon test could not be performed.

Under roentgen therapy the glands in the various areas receded. The patient was seen at frequent intervals, but it was not until eleven months later that a tumor was demonstrated in the nasopharynx. This region had been examined carefully several times previously. A biopsy of the nasopharynx gave a diagnosis of lympho-epithelioma. This was undoubtedly the primary tumor. A course of supervoltage roentgen therapy caused disappearance of the nasopharyngeal tumor. When the patient was last seen, four months later, there were no evidences of recurrence and he appeared well.

These two positive tests in cases which as far as we could determine were not of Hodgkin's disease caused us to review critically the forty cases in which tests had been made. At that time eight cases of Hodgkin's disease had been studied, and in all but one the Gordon tests had been positive. There were thirty-two controls, and in all except the two cases reported the tests were negative. In an attempt to correlate the histologic structure of the lymph nodes with the response in the rabbits it became evident that the emulsions giving a positive reaction were from nodes rich in eosinophils regardless of the other histologic changes. In order to test the significance of this observation several experiments were performed with suspensions of other human tissues handled in a comparable manner.

Extracts of a cutaneous tumor from a patient with typical mycosis fungoides and from the renal cortex of a patient with subacute glomerular nephritis, both containing numerous eosinophils, gave positive Gordon reactions. Friedemann²³ reported that normal human kidney did not elicit this reaction. It may be proposed that this observation indicates the close identity of mycosis fungoides and Hodgkin's disease, but I do not think that it necessarily does.

Rabbit tests were positive after injection of extracts of leukocytic cream separated from the blood of two patients with trichinosis, one with a blood count of 11,000 leukocytes, 31 per cent eosinophils, and the other with a count of 14,200, 54 per cent eosinophils. I have not experimented further with leukocytic creams, but others²⁴ have found that any suspension of human leukocytes containing as many as "2,000 eosinophils per cubic millimeter produced a paralysis indistinguishable from that seen in the positive Gordon test, while the numbers of any other type of white blood cell appeared to exert no such influence."

I was curious as to the effects that might be produced by injection of another type of eosinophilic cell, such as that found in the hypophysis. Extracts of the anterior lobe of the hypophysis from a person who had died of an abscess of the lung and empyema and from a patient who had died of bronchopneumonia both gave negative reactions in animals.

During this period nodes from ten more patients with lymphadenopathy were tested, bringing the number of cases to the fifty reported. A study of all the microscopic slides showed remarkable agreement of positive Gordon tests and nodes generously infiltrated with eosinophils. Sections of the nodes from the three patients said by clinicians and pathologists to have Hodgkin's disease but with negative Gordon reactions

revealed exceedingly rare eosinophils. One of these patients died three months after the tests were made and another within a year, and the third is following the usual failing course of Hodgkin's disease.

Eosinophils were remarkably few in number or absent from the sections from the thirty-five control patients giving negative Gordon reactions. Three controls had nodes which histologic examination showed to be tuberculous. When suspensions of these nodes were injected into rabbits, two gave a negative reaction but the third rabbit grew loath to move, showed signs of meningeal irritation, lost weight and died in two and a half months. It did not exhibit the typical sequence of events of a positive Gordon reaction. An autopsy revealed caseous tuberculous lesions in the lungs containing many acid-fast bacilli. There was mild non-specific lymphocytic infiltration of the meninges, but a definitely tuberculous lesion was not demonstrated in the brain. Bacteriologic examination of the original lymph node had shown acid-fast bacilli and *Streptococcus viridans*. The latter had been destroyed by phenol, and it was hoped that the tubercle bacilli were also destroyed, but apparently they were not. Since Manson²⁸ reported positive Gordon tests with nodes from two patients with tuberculosis, I wonder whether his rabbits showed tuberculous lesions of the central nervous system which could possibly have accounted for their neurologic signs or whether there were many eosinophils present in the nodes.

The papers of Gordon and Van Rooyen should be consulted regarding the properties of the pathogenic agent present in emulsions of glands from patients with Hodgkin's disease. I add a few personal observations on the nature of this agent in verification of some of their work.

An autopsy furnished a large amount of typical Hodgkin's lymph glands heavily infiltrated with eosinophils. The patient had received all the roentgen therapy that could be tolerated with safety. Extracts of the lymph glands elicited positive Gordon reactions in three days, with death of the animals in from five to twenty days. One extract was sterilized by long centrifugation, another with phenol and a third by passage through a Seitz filter according to the technic of Van Rooyen.²⁹ All rabbits gave positive reactions on the third day after inoculation. Sixty days later a portion of desiccated gland was made into a 1 to 50 suspension in broth at a p_H of 7.2. One part of the extract was frozen in a test tube in carbon dioxide at -57°C . for ten minutes and then thawed; a second part was exposed in an open vessel to 10,000 roentgens, equivalent to approximately 20 skin doses, and a third part was untreated. All produced positive reactions in rabbits on the third day. It is apparent that roentgen therapy of the living tissue and of the extracted tissue does not inactivate the agent responsible for the reaction in rabbits. Twenty-four months later this desiccated material was still capable of producing a typical Gordon reaction in rabbits when given intracerebrally and intravenously or intracerebrally only. Brains and spinal cords from animals paralyzed by extracts from this patient and from others uniformly failed to produce the Gordon reaction when inoculated into other rabbits either immediately or after extraction.

Kelser and King⁵ made careful histologic studies of the brains of guinea pigs and rabbits exhibiting the paralytic syndrome after inoculation with extracts of human and monkey bone marrow. They described

reactions occurring locally at the site of injection and also more general widespread effects. The local reaction was similar to that resulting from the introduction of any destructive agent but more severe than that expected from the small amount of material injected. There were central necrosis, hemorrhage and large numbers of Gitter cells, with a peripheral zone of cytologic degeneration, vascular proliferation, perivascular glial infiltration and a mononuclear type of mild meningeal inflammation. The remote reactions were most strikingly seen in the cerebellum, where there was severe and widespread injury to the Purkinje cells. One observes a similar condition in the brains of rabbits exhibiting paralysis after inoculation with extracts of lymph nodes from patients with Hodgkin's disease. Although this phase of the problem will be more carefully detailed at a later date, I reproduce at this time examples of the lesions found. Figure 1 illustrates a field from the inoculation area in the cerebral cortex of a paralyzed rabbit. There are central necrosis, a few Gitter cells, an increase in microglia and a slight

Fig. 2.—The cerebellum of a paralyzed rabbit, showing degenerative changes in the Purkinje cells (slightly reduced from a photomicrograph with a magnification of 160 diameters).

increase in perivascular glial cells. Figure 2 shows part of a folium of the cerebellum of a paralyzed rabbit, with various degenerative changes in the Purkinje cells. These cells are swollen and vacuolated and exhibit neurophagia. Several are pale staining or are mere shadows, while others have completely disappeared. There are fields in the same specimen in which no Purkinje cells can be found.

Kelser and King said that the symptoms of the affected animals are the result of a widespread functional involvement of the nervous system, caused by a chemical or enzymatic agent apparently of leukocytic origin and not by a virus.

COMMENT

The data presented is in confirmation of the conclusions of Turner, Jackson and Parker²⁹ and indicate the close etiologic relation of the eosinophil to the Gordon and Friedemann phenomena. Other writers have published evidence in support of this relation but have attached no significance to their observations.

Wurm^{2m} reported nine cases of clinical and histologic Hodgkin's disease in which the Gordon tests were negative and noted that the sections were singularly free of eosinophils. Van Rooyen⁵ reported a positive Gordon test with material from a boy who clinically had Hodgkin's disease but histologically displayed only marked eosinophilia, with no other features sufficiently characteristic to warrant such a diagnosis. Our compilation of 192 cases of Hodgkin's disease shows that the Gordon test was positive with approxi-

4. Histologic studies have already shown that eosinophils are easily demonstrable in the glands of some 70 per cent of patients with Hodgkin's disease, and it is in the same percentage of cases that the Gordon test is positive. Apparently it is positive only by virtue of these cells.

5. The Gordon test is of no more practical value in the diagnosis of Hodgkin's disease than is the finding of eosinophils in the lymph nodes.

Results with the Gordon Test

| Type of Material | Histologic Diagnosis | Number of Cases | Gordon Test | |

mately 70 per cent of the lymph nodes. This is in complete agreement with the critical histologic studies of Pullinger¹¹ on the lymph nodes from thirty-nine patients with Hodgkin's disease, in which eosinophils were found in 71 per cent of the nodes.

It follows that the Gordon test is of little or no value in the practical diagnosis of Hodgkin's disease. It is true that the test is positive with 70 per cent of the lymph nodes from patients with the disease and negative with 98 per cent of other lymph nodes, but this apparently is due only to the eosinophils present and undoubtedly has nothing to do with the disease itself.

The exact nature of the pathogenic agent still remains unknown. It apparently is not a virus or living agent. I favor the theory that it is a chemical or enzymatic agent.⁶ It has been suggested that it may be similar to the Charcot-Leyden crystals, which are looked on as a derivative of the primate eosinophil.^{2m} Future studies may be enlightening as to this agent and as to the eosinophil itself.

SUMMARY

1. In my series the Gordon test was positive in ten of thirteen cases of Hodgkin's disease (77 per cent) and negative in thirty-five of thirty-seven control cases of various lymphadenopathies (95 per cent). These cases being included, the Gordon test has been reported positive in 70 per cent of 192 cases of Hodgkin's disease and negative in 98 per cent of 251 control cases.

2. Histologic sections of the lymph nodes eliciting the positive reactions showed numerous eosinophils, while the nodes associated with the negative reactions contained very few or no eosinophils.

3. Extracts of human tissues and leukocytes which were from patients who definitely did not have Hodgkin's disease but which contained many eosinophils caused reactions in rabbits indistinguishable from those caused by the lymph nodes from patients with typical Hodgkin's disease. This supports the theory that Gordon's agent and Friedemann's agent are identical and are apparently derived from the eosinophil.

ABSTRACT OF DISCUSSION

DR. F. H. LAMB, Davenport, Iowa: I should like to ask Dr. McNaught what percentage of the cases in which the lymph nodes were tested were from living patients, and how that percentage compares with those from the dead.

DR. JAMES B. McNAUGHT, San Francisco: Lymph nodes from two of the thirteen cases of Hodgkin's disease submitted to the Gordon biologic test were obtained at autopsy. Both gave positive tests. The other eleven specimens were biopsies. Eight of these were positive and three were negative. Other than the simple tests, most of the experimental work was performed on autopsy material, which obviously was available in larger quantities.

Clinical Notes, Suggestions and New Instruments

VINETHENE BURN

SYDNEY S. LYONS, D.D.S., M.D., NEW YORK

Vinethene, since its introduction to clinical anesthesia in 1931, has been the subject of numerous reports. A review of these articles failed to reveal any reference to the possibility of this agent producing a skin burn.

Appearance of burn two days after administration of anesthetic.

Herein is a brief description of a clinical case of a burn on the face which occurred following the administration of vinethene anesthesia.

REPORT OF CASE

A white boy, aged 13, from the psychopathic service, was brought to the dental clinic for extraction. The history and physical examination were irrelevant. The skin of the face was apparently normal. The patient was anesthetized in a dental chair. Vinethene was administered by an open drop

From the Division of Anesthesia, Bellevue Hospital.

technic. This method consisted in cupping a regulation 4 by 4 inch hospital gauze square (40/44 mesh, six thicknesses) over the nose and mouth to form an evaporating surface. Vinethene was then dropped on the gauze from freshly opened original 25 cc. containers until surgical anesthesia was obtained. Less than one minute after induction was begun the gauze was rearranged, permitting the surgeon access to the mouth. Extraction required twenty-one minutes, during which time vinethene was constantly dropped on the gauze held in place by the anesthetist's thumb and finger. After completion of the operating procedure the gauze was removed. A total of 46 cc. of anesthetic agent had been used. Recovery from anesthesia was complete in less than two minutes and the patient soon walked to the ward, accompanied by an attendant. On his arrival he complained of a sore cheek. Some six hours later, a vesicle was noted and examination the following day revealed a superficial lesion lateral to the left ala nasi, which was evidently a burn. The site of the cauterized area corresponded to the position over which the anesthetist placed his thumb to hold the gauze. Its configuration resembled the part of the thumb which had kept contact between the gauze and the face. The burn was treated with boric acid ointment and healing was complete in seven days. A photograph taken on the second day after anesthesia is reproduced.

This case illustrates that vinethene may cauterize the skin as does ether, when it is confined to an area from which it cannot evaporate easily. If pressure is applied to the area it may enhance the possibility of a burn. It is advised that with technics similar to that used in the case reviewed, the skin be protected by applying a bland ointment before administering anesthesia.

A MICROSCOPIC PRECIPITIN TEST FOR TYPING PNEUMOCOCCI

ISABELLE G. SCHAUB, A.B., AND ROGER D. REID, PH.D., BALTIMORE

The rapid typing of pneumococci is becoming increasingly important with the development of therapeutic serums for the various types. The Neufeld method is admirably suited when the organisms are present in sputum, but difficulties are encountered when typing is attempted from cultures. The macroscopic agglutination of cultures requires the use of pipets and test tubes, and the quantity of serum required represents considerable expense. We have employed a microscopic precipitin technic by which the pneumococci can be typed from cultures quickly and with a very small amount of immune serum. The technic proposed by Brown¹ for grouping the hemolytic streptococci has been adapted for this purpose.

PREPARATION OF THE ANTIGEN

Cultures of pneumococci from blood, spinal fluid or other sources taken during life or at autopsy may be grown in meat infusion broth containing a few drops of serum or ascitic fluid² incubated at 37 C. for from six to eighteen hours. The culture is lysed by the addition of two drops of a 10 per cent aqueous solution of sodium desoxycholate (containing 1:50,000 merthiolate to prevent the growth of molds) per cubic centimeter of

culture.³ In from fifteen to thirty minutes the organisms are dissolved, and tests have shown that the lysate is sterile. The antigen is now ready for use. In some instances an excess of sodium desoxycholate in the presence of serum will cause the culture medium to gel. This may be liquefied by warming slightly without decreasing the efficiency of the test.

PREPARATION OF THE TYPING SERUM

For making this test, horse antipneumococcus serum such as is used for macroscopic agglutination tests, diluted 1:10 in

A, negative precipitin reaction; B, doubtful cross reaction; C, typical positive reaction.

physiologic solution of sodium chloride, is used. Such dilutions have been found satisfactory after refrigeration for as long as six weeks.

Rabbit antipneumococcus serum as prepared for the "quellung" test, diluted 1:1 in salt solution, has been used, but the reaction takes place more slowly, sometimes requiring from one to two hours for marked precipitation to take place. The reaction with the diluted horse serum takes place rapidly, and readings can be made after from fifteen to thirty minutes. By adding 1 per cent aqueous methylene blue to the horse serum the reading of results is facilitated, although the dye is not essential to the test. Dye is already present in the rabbit "quellung" serum.

Attempts were made to place the organisms into groups by means of commercially prepared "quellung" grouping serums or by mixing the typing serums prepared from horses in proportions based on the titer of the species antiserum, but results obtained were not sufficiently uniform to be considered satisfactory.

TECHNIC OF THE TEST

The Petri dish-hanging drop technic described by Brown is used for making the test. A disk of moist filter paper is placed in the lid of the dish. The bottom of the dish is ruled on the bottom surface with a wax or diamond pencil, providing sixteen 12 mm. squares. In the performance of the test two Petri dishes are required for each organism to be typed. In one dish the antigen is set up against each of the fifteen types of antiserum (diluted), the sixteenth square being used for an antigen-salt control. In the second dish the remaining type antisera are set up. It has been found most practicable to add one platinum loopful of the antigen to each of five squares and mix with them an equal amount of the appropriate typing serums, and then to proceed with the next five squares in the same manner. This prevents drying of the loop of antigen before it is possible to add the antiserum, as is likely to happen if the antigen is placed in all fifteen squares before the antisera are added. A 2 mm. loop of platinum rather than one of the platinum substitutes is recommended. The loop should be thoroughly flamed and cooled each time before being introduced into the serum.

READING OF RESULTS

The mixtures of serum and antigen are held from fifteen to thirty minutes and readings are made with the 16 mm. objective of the microscope, the light from the condenser being

3. This method for the preparation of the antigen does not actually introduce an additional step, since solubility in sodium desoxycholate is one of the first tests to be made in the identification of pneumococci. Leifson, Einar: The Use of Sodium Desoxycholate for the Identification of Pneumococci, J. A. M. A. 104: 213 (Jan. 19) 1935.

From the Department of Pathology and Bacteriology, Johns Hopkins University.

The Division of Laboratories and Research, New York State Department of Health, the Bureau of Laboratories, New York City Department of Health, the Bureau of Bacteriology, Maryland State Department of Health, and Sharp and Dohme, Philadelphia, supplied the cultures and antisera for this investigation.

1. Brown, J. H.: A Simplified Method for Grouping Hemolytic Streptococci by the Precipitin Reaction, J. A. M. A. 111: 310 (July 23) 1938.

2. Other mediums such as meat infusion broth with or without blood may be used. A small amount of dextrose may be added to stimulate growth, but in this case it is necessary to adjust the reaction of the medium by the addition of sodium hydroxide until the indicator, bromothymol blue, is bluish green, indicating that the solution is slightly alkaline before the sodium desoxycholate is added. The cultures may also be grown on infusion agar slants containing 10 per cent rabbit blood and the organisms washed off with sterile saline solution and lysed. A satisfactory antigen has also been prepared by using the peritoneal washings from a mouse previously injected with infected material such as sputum.

allowed to pass through the moist filter paper. Gentle rotation of the plates hastens the formation of large clumps of precipitate. The appearance of large clumps of precipitate (C in the illustration) indicates a positive reaction. Negative results are indicated by the absence of such clumping (A). Doubtful or questionable results are seldom encountered but can be eliminated by comparison with the control and a known positive. In using this technic for the first few times it is suggested that known positives and negatives be set up as controls to familiarize the worker with typical reactions.

Infrequently, though occasionally, cross reactions occur. These may be distinguished from typical positive reactions with a little experience. Such a doubtful cross reaction is shown in B. There appears to be no advantage in incubation or refrigeration of the mixtures.

RESULTS

We have made repeated tests on cultures belonging to all the known types of pneumococci, including the Cooper strains. We have also identified and made repeated tests on fifty-five cultures taken from infections and at autopsies. Unknown cultures have been checked by other methods and complete agreement was found in every instance.

With the method described, cultures of pneumococci may be typed in a much shorter time than with the macroscopic test; more reliably, in our opinion, than with the "quellung" test; at a minimum expense for serum and antigen, and with the advantage of working with a sterile antigen.

Special Clinical Article

HODGKIN'S DISEASE

SIXTY CASES IN WHICH THERE WERE INTRA-
THORACIC LESIONS

CLINICAL LECTURE AT SAN FRANCISCO
SESSION

C. B. WRIGHT, M.D.
MINNEAPOLIS

In 1832 Hodgkin reported seven cases of unusual glandular swellings. His description was clinical. In 1865 Samuel Wilks reported thirteen similar cases and named the condition "Hodgkin's disease." In 1926 Herbert Fox¹ reexamined Hodgkin's pathologic specimens and found that of the seven cases three were of Hodgkin's disease, one was of syphilis, one was of tuberculosis and one was probably of lymphatic leukemia. For the next seventy years tuberculosis followed Hodgkin's disease like a shadow. It is difficult to realize today what a common condition glandular tuberculosis was previous to modern food sanitation and the tuberculin testing of cattle. In 1902 Dorothy Reed definitely differentiated Hodgkin's disease from tuberculosis. The two diseases are still occasionally found associated. It is very interesting to compare this condition with that in our series. Four patients had calcified nodes, one had active tuberculosis and Hodgkin's disease in the same mediastinal gland and one had terminal tuberculous pericarditis.

Since 1902 pathologists have added much confusion to the literature with a great variety of names for this disease. Wallhauser² found fifty different names for Hodgkin's disease in 1933.

Read in the Medical Division of the General Scientific Meetings at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 14, 1938.

1. Fox, Herbert: Remarks on Microscopical Preparations Made from Some of the Original Tissue Described by Thomas Hodgkin, 1832, Guy's Hosp. Rep. **86**: 11 (Jan.-April) 1936.

2. Wallhauser, Andrew: Hodgkin's Disease, Arch. Path. **16**: 522-523 (Nov.) 1933.

There is no doubt that biopsy is the most exact method of diagnosis of this disease in the living. This presupposes that the specimen furnishes the pathologist with tissue containing the typical lesions. Therefore it should be taken from a characteristic gland. It should be taken, of course, under the most careful antiseptic conditions, as there is nothing more difficult to deal with than the complication of an infected sinus. When Dorothy Reed cells are present they are pathognomonic. In many slides there are large reticulum cells either singly or in groups, not one of which, however, is a typical Dorothy Reed giant cell. According to Bell³ the increase in the number and size of the reticulum cells is the most constant feature of the disease. Fibrosis is usually present and is usually regarded as indicating an advanced stage, but it may be found early in the disease. In some cases fibrosis is prominent in both large and small lymph nodes; in others it is inconspicuous. The cellular forms of Hodgkin's disease blend with leukemia, and in rare cases one finds a leukemic blood picture with typical Hodgkin's disease in the lymph nodes. There is a similar blending with lymphosarcoma and leukemic reticulo-endotheliosis.

I have reviewed sixty cases of Hodgkin's disease, in all of which, during the period of observation, there were intrathoracic complications; all had been observed long enough so that there was a fairly good clinical history and a physical examination had been made. All the patients had roentgen treatment and were under observation for a considerable period.

Figure 1 shows the first indications of the disease as recorded in the chart from the physical examination or in the history taken from the patient or reported by the referring physician.

The patients did not all have intrathoracic lesions on first examination. Some had them then and the rest acquired them later, while they were under observation; many had complications in other parts of the body. In addition to the more common conditions shown in figure 1, there was a variety of unusual conditions.

Fig. 1.—First indications of Hodgkin's disease in sixty cases.

In two cases there was jaundice. In one case it was present for about two weeks and then cleared up. In the second case there was a history, on admission, of jaundice coming on about a week after removal of the gallbladder for chronic cholecystitis and cholelithiasis. Glands were later found in the neck which on biopsy proved to be typical of Hodgkin's disease. There were two fatal cases of intestinal perforation due to Hodgkin's disease. There was one case of involvement of the spinal cord with paralysis. There

3. Bell, E. T.: Textbook of Pathology, Philadelphia, Lea & Febiger, 1938.

was one case of extensive involvement of bone and one case of involvement of the skin.

In one case the disease simulated nontropical sprue:

CASE 1.—A woman aged 63 began in 1932 to have diarrhea, generalized weakness and shortness of breath on exertion, and she lost 50 pounds (23 Kg.) in weight. In the fall of 1935 pain in the upper part of the abdomen developed. The liver and spleen became palpable; she had marked secondary anemia, and the white blood cell count was low. The skin was leathery, with a light diffuse pigmentation. No gastrointestinal lesions were found by x-ray study, and a diagnosis of cancer of the liver was suggested. However, with a generous diet and liver the patient gained 20 pounds (9 Kg.) and felt well. Her blood count rose to normal. One year later the diarrhea returned. Three months later vomiting, partial paralysis of the legs, weakness of the hands and slow scanning speech developed. Vibration and the tactile senses were normal. All serologic tests were negative except that for the bacillus of Flexner. The patient had some soreness of the mouth and secondary anemia. No eosinophilia was noted in any of her blood examinations. At times she had a fever, and in her final illness her temperature was as high as 103 F. No superficial glandular enlarge-

ments were noted at any time. A clinical diagnosis of nontropical sprue was suggested. The patient died five years after her first symptoms. Postmortem examination showed Hodgkin's disease of the mediastinal nodes, marked Hodgkin's disease of the spleen, tuberculous pericarditis, hyperplasia of the bone marrow, fatty liver with necrosis, chronic benign ulceration of the rectum and pigmentation of the skin.

At no time had she any definite symptoms referable to the chest. The brain and cord were not examined at autopsy.

Fig. 2 (case 3).—Invasion of the left lung and very large mediastinal glands.

Itching is common in Hodgkin's disease and occurs without lesions other than excoriations:

CASE 2.—A woman aged 41, who complained for eight months of intense itching of the skin, had been treated without improvement. On examination she was found to have enlarged glands in the left supraclavicular region, and biopsy showed typical Hodgkin's disease. X-ray examination showed enlarged glands in the mediastinum. The itching grew less with high voltage roentgen therapy, and the glands disappeared.

Desjardins⁴ expressed the opinion that pruritus and cutaneous lesions could be cured by irradiation over the liver. Roentgen therapy does not always relieve the itching. Kasaback and McAlpin⁵ relieved two of five patients with roentgen treatment over the liver.

Certain clinical and laboratory observations have been used as criteria for the diagnosis of Hodgkin's disease. Discrete, painless and slowly developing enlargement of the peripheral glands is the most common clinical characteristic. Practically all patients have fever.

LABORATORY STUDY

In only eleven of the sixty cases was there eosinophilia. The degree varied from time to time during the

observation. The highest percentage of eosinophils in any case was 24, and in many of the cases no eosinophils were found in the circulating blood. Secondary anemia is a fairly constant sign in the cases of very active involvement. However, in many cases in which the condition seemed severe the blood counts were within normal limits or showed only a slight degree of anemia. The anemia seemed to have no relationship to roentgen treatment; in fact, many of the patients showed improvement in their blood after this procedure. Leukocytosis was a not uncommon manifestation; white blood cell counts as high as 20,000 or 30,000 were recorded. Leukopenia was found not infrequently; the lowest count recorded was 2,300. The degree of leukopenia varied in individual patients. There was no uni-

formity in any of the blood counts, as they varied with the same patient at different times and with different patients.

In cases in which tissue is not accessible for biopsy a specific test of some kind would be most desirable. Gordon⁶ devised a test which he thought was specific for Hodgkin's disease. It consisted of inoculating broth suspensions of Hodgkin's tissue into the brain of rabbits or guinea pigs, producing a characteristic paralysis. His work was verified by other observers. Friedman showed, however, that the same type of paralysis of the same kind of animals could be produced with extracts of bone marrow, spleen or glands. Turner and Jackson⁷ concluded that this test is positive because of the presence of eosinophils and that it would be negative when eosinophils were absent. In the present series three patients were tested by this method, and the results with two were positive.

Fifty-four patients had superficial glandular enlargements, and biopsies were performed during their period of observation. Five patients had biopsies or were examined post mortem elsewhere. One patient had no

superficial glands showing at any time and therefore no biopsy. In one case the biopsy did not show Hodgkin's disease but autopsy did.

INTRATHORACIC LESIONS

The intrathoracic lesions are of four varieties: (1) enlargement of the mediastinal glands, (2) involvement of the pulmonary parenchyma, (3) involvement of the pleura and (4) combinations of these regional types.

In fifty-seven cases enlarged mediastinal glands were demonstrated by roentgenogram. Twenty-one patients had parenchymal involvement, and eighteen of these had also enlarged mediastinal glands. Three of these patients had parenchymal lesions only. Seventeen patients had pleural effusion; all of these had mediastinal enlargements. Seven had pleural effusion and involvement of the mediastinal glands.

REPORT OF ADDITIONAL CASES

CASE 3.—A man aged 49, who began to have symptoms in 1932 in the form of influenza of the stomach with productive cough, was admitted to the hospital May 8, 1934. It was discovered that he had a tumor which at first was thought to be a bronchiogenic carcinoma. Biopsy of material from a bronchus, however, resulted in a diagnosis of subepithelial fibrosis. Biopsy of an enlarged lymph gland in the axilla showed only hyperplasia. A roentgenogram (fig. 2) showed invasion of the left lung and very large mediastinal glands. The growth responded so remarkably to roentgen treatment (fig. 3) that the diagnosis was changed to lymphosarcoma and later to Hodgkin's disease. The patient was discharged June 2, 1934, and died September 9. No autopsy was performed.

CASE 4.—A girl aged 11, whose first symptoms appeared in October 1930 in the form of swollen glands, began to cough in November 1930. She was admitted to Glen Lake Sanatorium, Oak Terrace, Minn., April 24, 1931, when biopsy resulted in a diagnosis of Hodgkin's disease. The glands enlarged were the left cervical and later the left axillary. Examination of the chest revealed decreased tactile fremitus, dullness and diminished breath sounds over the left portion. The tumor responded very well to roentgen treatment, but the patient died June 24, 1932. No autopsy was performed.

Fig. 5 (case 7).—Extensive tumor.

lateral aspect of the left calf. The chest was clear on physical examination. The patient died November 13, two days after biopsy. No autopsy was performed.

CASE 6.—A man aged 36, who began to have symptoms in September 1933 with pain in the left hip, had experienced marked itching of the skin since 1937. The diagnosis, made by biopsy at the University of Minnesota in January 1938, was Hodgkin's disease. The glands enlarged were the supraclavicular and submaxillary and those in the groins. The thigh was swollen and the left ilium extensively involved (fig. 4). A roentgenogram of the chest showed areas of increased density

in both lung fields, involvement of several ribs and of the left scapula and bilateral involvement of both lungs. The patient died Feb. 6, 1938.

CASE 7.—A girl aged 15 had her first symptom in 1936 in the form of itching, which had been diagnosed elsewhere as scabies. A diagnosis of Hodgkin's disease was made by biopsy at Ancker Hospital, St. Paul, Dec. 15, 1936. The glands enlarged were the cervical, inguinal and epitrochlear. A roentgenogram of the chest (fig. 5) showed enlarged hilar shadows on both sides and mediastinal adenopathy. The itching decreased and there was marked regression of the mediastinal masses with roentgen treatment (fig. 6). The patient was still alive March 10, 1938.

Fig. 6 (case 7).—Almost complete absence of tumor after roentgen treatment.

CASE 8.—A man aged 20, whose first symptoms, in 1924 or 1925, indicated that he had pleurisy with effusion, was well from that time to about November 1928, when he felt weak and had pain in the right axilla. A diagnosis of Hodgkin's disease was made by biopsy at the University of Minnesota Dec. 27, 1928. The supraclavicular glands were enlarged. Examination of the chest showed increased tactile fremitus, impaired resonance in the upper part of the back on both sides and rales. A roentgenogram of the chest showed a large mass in the right hilus attached to the anterior wall of the chest, posterior to the level of the trachea, and thickening of the pleura on the left side. After treatment the tumor on the right side practically disappeared. Later there was continued improvement on the right side but more evidence of parenchymal involvement at the base of the left lung. The patient died Nov. 8, 1933.

CASE 9.—A youth aged 17 had his first symptoms, consisting of pain in the left shoulder and colds, in May 1934. Swelling in the neck began in August. No biopsy was reported. The patient was admitted to the hospital November 24. The glands enlarged were the left anterior cervical and the right inguinal. Examination of the chest showed dullness over the entire left side. The lower border of the left lung could not be determined. Superficial veins over the chest were dilated. A roentgenogram of the chest showed a large mass, which looked like lymphosarcoma, involving the left side of the mediastinum and another definite area in the right lung. The patient died Dec. 24, 1934; the diagnosis at autopsy was teratoma.

CASE 10.—A man aged 52 had as his first symptom a mass in the upper part of the abdomen and dyspnea, which appeared in September 1935. A tumor was removed in January 1936 and was diagnosed as lymphosarcoma. The patient was admitted to the hospital February 19. One gland was enlarged. A roentgenogram of the chest (fig. 7) showed a suggestion of aneurysm of the descending aorta because of expansible pulsation, metastases in the right pleura and bilateral pleural effusion. When last seen, Oct. 10, 1936, the patient was not responding well to treatment; his condition was worse and the tumor was larger. Autopsy showed a Hodgkin growth completely surrounding the aorta and giving an expansile appearance.

CASE 11.—A man aged 33 had as his first symptoms, in 1928, a sharp pain in the right side of the chest and a temperature between 101 and 102 F. in the afternoon. There was recurrence with cough and effusion in the chest in April 1929. In October 1929 a tumor mass in the mediastinum was found by means of x-ray examination. No biopsy was reported. On admission to the hospital no superficial adenopathy was found. Examination of the chest showed impaired resonance and

increased fremitus over the right side. A roentgenogram showed a small amount of fluid in both sides of the chest and a large mass in the right side of the superior mediastinum, lobular and irregular. The patient was discharged from the hospital Feb. 22, 1930, and died July 10, 1931. Autopsy revealed no Hodgkin's disease, but there were active pulmonary and mediastinal node tuberculosis and amyloid disease.

CASE 12.—A man aged 54, who had as his first symptoms cough and cold, some mucoid sputum, loss of weight and a tendency to tire easily, was admitted to the hospital April 10, 1930. The Wassermann reaction was positive. Fluoroscopic examination of the chest showed a large aneurysm, not pulsating, which extended to the right and left of the mediastinum. A roentgenogram of the chest (fig. 8A) showed an aneurysm of the transverse and descending portions of the arch of the aorta, possibly a double aneurysm, and displacement of the aorta. The patient was last seen Jan. 16, 1931.

CASE 13.—A man aged 21, whose first symptoms were cough, swelling of the face and neck, loss of weight, weakness and shortness of breath, which he had experienced since January 1930, was admitted to the hospital April 9, 1930. Biopsy of the glands in the neck resulted in a report of Hodgkin's disease. The patient had one terrific attack of dyspnea and cyanosis, during which he had to be put in an oxygen tent and tracheotomy was performed. He improved with roentgen therapy. Nodes were present on the right side at the angle of the jaw, there was a mass of glands in the anterior triangle of the neck and veins of the upper part of the chest were dilated. A roentgenogram of the chest (fig. 8B) showed a large lobulated mass extending from the superior mediastinum into both lungs, bilateral pleural effusion and pulmonary abscess. The patient was last heard from Aug. 8, 1930.

THERAPY

Before considering the therapy of Hodgkin's disease I wish to quote from Osler's description published in 1909. He suggested the surgical removal of localized glandular swellings when they are not too large. He also recommended the use of solution of potassium

Fig. 7 (case 10).—Barium sulfate in the esophagus with relation to the growth.

arsenite. At that time x-rays were just beginning to be used and in some cases the condition had responded well. However, he concluded:

There are acute cases in which the enlargements spread rapidly and death follows in three or four months. As a rule, the disease lasts two or three years. Remarkable periods of quiescence may occur in which the glands diminish in size, the fever disappears and the general condition improves. Even a large group of glands

may almost completely disappear or tumor mass on one side of the neck may subside while the inguinal glands are enlarging.

No more is known today about the cause of Hodgkin's disease than Osler knew in 1909. Until the cause is known treatment will be empiric. Surgical intervention at present is seldom used. Solution of potassium arsenite is not mentioned in modern textbooks. The only treatment considered seriously is irradiation.

Reports are appearing from time to time in which the results of roentgen therapy are estimated. Kasaback and McAlpin, in a recent report on a large series of cases, emphasized diet as well as roentgen therapy. Regarding the latter one may conclude:

First, that there is general agreement that high voltage roentgen therapy is not harmful to the patient in doses sufficient to affect this disease.

Fig. 8.—A, case 12, syphilis with aneurysm; B, case 13, mediastinal Hodgkin's disease.

Second, that the response to high voltage roentgen therapy of Hodgkin's disease, lymphosarcoma, with which it is most often confused, and to a lesser degree lymphatic aleukemia is as a rule definite and in cases in which the growths are producing pressure on vital organs may be life saving.

Third, that general irradiation of glands and bone is no longer advocated as a prophylactic measure.

Fourth, that the plan now is to treat local manifestations of the disease thoroughly as they arise.

Sensitivity of growths to treatment varies, and the development of resistance to x-rays seems likely. Some patients have this little understood resistance from the beginning; others seem to acquire it after repeated treatment, and the disease rapidly spreads.

The knowledge gathered from tumor clinics will increase, and clinicians should do all they can to assist in therapy. Patients respond well to blood transfusions when anemic, and this procedure also may be life saving. The general edema will often respond remarkably to mercurial diuretics. The diet and general hygienic surroundings should be carefully supervised. One must keep in mind the fact that this disease, which is now generally considered some form of malignant process in the reticulo-endothelial system, may, as some authorities still think, be parasitic in origin.

It is true that the condition in many cases is acute and resists all forms of treatment. The great majority of patients, however, live a considerable length of time, and a few live many years. By means of the available agencies the average period of life can probably be prolonged.

STATISTICAL SUMMARY OF RESULTS OF TREATMENT IN SIXTY CASES

Forty-five of the sixty patients observed were followed until their death. The average duration of life was forty months. Twenty-three of the patients lived over forty months; the average length of life was sixty months. Twenty-one patients lived less than forty months; the average length of life was twenty months. Two patients were lost track of and presumably died, but they are not considered.

For the thirteen patients now living, the average length of the disease is fifty months. Seven of these patients have had the disease seventy-two months. The majority are in fairly good health. Some are working, and others are in a condition of semi-invalidism.

An attempt was made to estimate the length of life after the onset of intrathoracic complications. In some cases there were in addition other complications. In the thirty-nine cases in which this estimate could be made, the average survival period was twenty-three months.

Kasabach and McAlpin found that the average survival period of thirty-eight patients adequately treated was five years and four months. Twenty patients inadequately treated survived three years and three months. In seven cases in which no treatment had been given the survival period was three years and one month.

In our series the shortest period from onset to termination was seven weeks. The patient was a woman aged 40.

The longest period was twenty-six years. In this case the diagnosis of Hodgkin's disease was made by Dr. E. T. Bell in 1910, and several biopsies subsequently confirmed the diagnosis. The patient was treated with roentgen radiation by Dr. Schons from time to time as growths appeared. On three occasions high voltage roentgen therapy apparently saved her life. At autopsy, in 1936, the lesions of Hodgkin's disease were found in the mediastinal and abdominal lymph nodes, liver, spleen and lungs. This case was not included in our statistics.

The following case illustrates the advanced stage in which patients come for treatment:

CASE 14.—A woman aged 51, with a history of easily palpable glands in the right side of the neck and right axilla for three years, when admitted to the Northwestern Hospital had general anasarca, fluid in both pleural cavities and abdomen, involvement of the mediastinal glands, enlargement of the liver and spleen, and large masses in the pelvis, which had led to the diagnosis of possible pelvic carcinoma with metastases. She had marked secondary anemia and a fever. Biopsy showed Hodgkin's disease. She was given salyrgan, blood transfusion and high voltage roentgen therapy over the chest and abdomen. She improved, the edema disappeared, the glands decreased in size, the liver and spleen became smaller and she left the hospital in fairly good health. She died a few weeks later of what appeared to be coronary occlusion. No autopsy was permitted.

Can a patient recover from Hodgkin's disease? The following case is illustrative:

CASE 15.—A man aged 59 had two operations for removal of enlarged glands in his neck. Biopsy by Dr. Bell indicated Hodgkin's disease. The glands recurred the same year and he was treated thoroughly over the neck by high voltage roentgen therapy. He is now 70, has had no subsequent treatment and has had no recurrence after eleven years.

CONCLUSIONS

Hodgkin's is a common disease. The cause is not known. The pathologic changes are well understood, and biopsy is the only sure way of making the diagnosis and should be done early and aseptically. High voltage roentgen therapy is often life saving and if used adequately will probably prolong life. Intrathoracic complications respond well to such therapy. Blood transfusions and mercurial diuretics are at times valuable. The general hygienic surroundings and diet are important.

VITAMIN C

METHODS OF ASSAY AND DIETARY SOURCES

OTTO A. BESSEY, PH.D.

BOSTON

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—ED.

The isolation, synthesis and development of practical methods of assay have given a great stimulus to the study of vitamin C.¹ More papers have appeared on methods of assay and distribution for vitamin C than for all the other vitamins combined. Therefore, no attempt is made here to present a systematic review of the literature. This has been done amply in the monograph by Sherman and Smith,² the yearly volumes of the *Annual Review of Biochemistry*,³ the bulletin of the United States Department of Agriculture on "Vitamin Content of Foods"⁴ and numerous reviews.⁵ The facts and comments presented in this review may serve to give a general idea of the present state of the subject.

BIO-ASSAY

Chemical methods have rapidly replaced vitamin C determinations by bio-assay for many types of investigations. However, the more specific animal tests continue to be necessary in order to avoid the risk of misinterpretation of the chemical tests.

Guinea pigs kept on certain purified diets fail to gain weight, and the specific pathologic changes of scurvy develop. The degree of protection or cure of the deficiency bears a quantitative relation to the amount of the vitamin administered. This principle forms the basis for biologic methods of vitamin C analyses.

*Preventive Method.*⁶—The technic of Sherman and his associates,² built on the experience of earlier investigators as well as their own studies, has continued to be the most generally used for animal assay purposes. Briefly, the method is as follows: Young guinea pigs are fed ad libitum a basal vitamin C-free diet which theoretically supplies everything necessary for their normal nutrition except vitamin C. Negative control animals are kept on the basal diet only, while other animals are fed graduated amounts of the material to be tested. After from six to ten weeks the degree of protection is estimated by a standard postmortem appraisal of the extent of hemorrhage, the beading and enlargement of the costochondral junctions, the softness of the mandibles, scapulas and ribs, and the looseness of the incisors. An amount of test material just

sufficient to afford complete protection from macroscopic scurvy is selected as a unit, and the results of all analyses are expressed in this unit.⁷ With experience and by the use of the survival period, weight and degree of scurvy, one can estimate the degree of protection afforded by the lower test levels, thus bringing into a quantitative rating those animals which are not completely protected. The general uniformity of the test can now be improved by comparing the rate of growth and the intensity of the macroscopic lesions in the test animals with those in a similar group of animals which received graded levels of pure ascorbic acid.⁸

Curative Method.—Harris⁹ and his associates have introduced a recovery method which is very useful. Less material is required and there is considerable saving in time and expense. Guinea pigs are kept on a basal diet as previously described, and after from two to three weeks animals are selected which show symptoms of scurvy and have begun to lose weight evenly. Graduated daily doses of the test material are then fed. After from ten to fourteen days the vitamin C value of the unknown is estimated by comparing the growth response with that obtained by feeding a like series of animals with graded amounts of pure ascorbic acid. Thus, with a continuous supply of guinea pigs acquiring scurvy, a test is completed in about two weeks. Care must be exercised in selecting animals for this test, because those which are "too sick" or which show signs of infection will not respond uniformly.

Tooth Method.—Höjer¹⁰ has proposed a method based on the observation that the degree of scurvy can be estimated by histologic examination of the teeth. A cross section of the root of a normal guinea pig incisor shows a row of long parallel odontoblasts surrounding the pulp and active in the formation of dentin. Höjer has described ten stages in the development of scurvy based on the amount of disorganization of the odontoblasts, the width, irregularity and structure of the dentin and the degree of calcification of the predentin. Key and Elphick¹¹ have described a modification in which, by the same criteria, they distinguish four degrees of scurvy. Using a large series of animals receiving graded doses of ascorbic acid, they plot the average degree of protection against the size of the dose, thus deriving a curve which shows the ratio of protection to dose at any level. When once established, this curve of reference may be used for calculations in successive assays, although it may be revised as additional data accumulate. An example will best show how this curve is used for a determination: A group of healthy growing guinea pigs (from 250 to 300 Gm.) were kept for a few days on a scorbutic diet plus greens. The test was started by withholding the greens. After three days one group of six animals received 0.9 mg. daily of ascorbic acid (International standard). Another group of six animals received 1 cc. of test material (orange juice) daily. Two guinea pigs were kept on the basal

diet only (negative control animals). After fourteen days all the animals were killed and the lower jaws fixed and decalcified in 5 per cent trichloroacetic acid, embedded in celloidin and sectioned just anterior and parallel to the first molar at right angles to the longitudinal axis of the mandible. This method gives a cross section of the incisor root, which runs parallel with the jaw at this point.¹² Sections were stained with hematoxylin and eosin and with connective tissue stains. The degree of protection was scored from 1 to 4 for each tooth and the average obtained for all animals on a like level. The guinea pigs receiving the orange juice showed an average protection of 1.3, while those receiving the ascorbic acid averaged 1.8. On the basis of a curve previously prepared as described by Key,¹³ the ratio of the protection in terms of ascorbic acid was found to be 0.62 divided by 0.90, which equals 0.69. Since, by definition, 1 mg. of ascorbic acid equals 20 international units, the potency of the orange juice equaled 13.8 international units per cubic centimeter. The curve of response is a device for calculating the relative potency of two materials which do not give an identical response.¹⁴ The feeding of a standard with each assay makes possible a correction for differences in sensitivity of different stocks.¹⁵

Comparison of Methods.—The chief source of uncertainty in such quantitative methods lies in the unavoidable variation of individual experimental animals and in the indefinite nature of the end point. Complete protection from scurvy or a definite degree of partial protection are conditions difficult to judge. The answer to the problem of which is the best method of bio-assay for vitamin C depends on the experience of the investigator, equipment available, material to be tested, time available, purpose of the assay and many other factors. In addition to the economy of time, the tooth method or the curative method is most useful if the quantity of test material is limited or subject to change by storage. The specificity of the tooth method and the Sherman method is an important feature lacking from the growth response method of Harris. On the other hand, the two former methods are liable to cause subjective errors in judging the degree of scurvy. The need of histologic experience and special equipment for the tooth method are objections to its general use, while the other methods are adaptable to the usual laboratory equipment. It is my experience¹⁵ and that of others¹⁶ that a longer test period than that recommended by Harris (e.g., four weeks) is necessary to obtain quantitative results comparable with those of other methods.

CHEMICAL METHODS

In general, chemical methods are more rapid and accurate than biologic methods but may lack specificity. However, when available and used with precaution they are of great help in many problems not subject to study by bio-assay.

7. A Sherman unit, or a minimum protective dose, is equivalent to 0.5 to 0.6 mg. of ascorbic acid.

8. International standards for assay purposes are obtained by application to the Protein and Nutrition Division, Bureau of Chemistry and Soils, U. S. Department of Agriculture, or to E. Fullerton Cook, Forty-Third Street and Woodland Avenue, Philadelphia.

12. It is important that the section be made at a consistent level of the tooth, otherwise the degenerating odontoblasts which normally occur in the incisal part of the tooth may be confused with the scorbutic process. In a longitudinal section of a guinea pig tooth may be observed dental tissue in all stages of development. In the root the odontoblasts are young, regularly arranged and active in the formation of dentin; as they proceed up the persistently growing tooth, a normal sequence of senility and degeneration occurs. Near the biting end of the tooth the odontoblasts normally have much the same appearance as those which are present in the root in scurvy.

The identification of vitamin C as a substance with striking reducing properties made it apparent that it had been studied previously as an unknown reducing substance in plant and animal tissues.¹⁷ Tillmans¹⁸ in studies of the freshness of natural foodstuffs had pointed out that a reducing substance is present in fresh fruits and vegetables which can be estimated by titration against an indicator, 2,6-dichlorophenolindophenol, and which appears to run parallel with their reported vitamin C content. The establishment of the identity of vitamin C by Waugh and King¹⁹ stimulated experiments by Tillmans and his associates,²⁰ Harris and his associates²¹ and Bessey and King²² which showed the close correlation between the amounts of vitamin C as determined by biological assay and by titration with 2,6-dichlorophenolindophenol in many plant and animal tissues. Additional evidence has supported the view that the titration test when properly used is reasonably specific for vitamin C in natural products.²³

The essential features of the test are an extraction of the material under examination with an acid-precipitating agent to remove certain interfering substances and to stabilize and bring into solution the vitamin C and subsequent titration of the vitamin with a standardized indophenol solution.

The use of 2,6-dichlorophenolindophenol²² to determine vitamin C is based on the fact that the colored

Reduction of indicator solution by vitamin C in acid solution.

indicator solution is quantitatively and rapidly reduced by vitamin C in acid solution to a colorless compound, as represented in the equation.

Indophenol Method.²⁴—The indicator solution is prepared by dissolving the required amount of dry dye in hot water (50 mg. for food and 10 mg. for blood or urine per hundred cubic centimeters). Although the solid dye is stable, the aqueous solution slowly changes even when kept in the refrigerator and for this reason should be restandardized frequently. It is standardized against a carefully prepared solution of ascorbic acid containing 20 ± 0.1 mg. per hundred cubic centimeters of 3 per cent metaphosphoric acid.²⁵ A good commer-

cial ascorbic acid is usually sufficiently pure for this purpose. However, the purity should be checked frequently by titration with iodine.²² One should dilute 5 cc. of the aforementioned solution to 100 cc. with 3 per cent metaphosphoric acid for standardizing the more dilute dye solution. The strength of the reagent is expressed in milligrams of ascorbic acid per cubic centimeter of indophenol solution.

Extracts of plant and animal tissues for vitamin C determinations are best obtained by thoroughly rupturing the cellular structures in metaphosphoric acid. The acid prevents the rapid oxidation of vitamin C due to enzymes²⁶ liberated by the macerated cells or by the presence of traces of certain metals.²⁷ Metaphosphoric acid²⁸ has replaced the use of other acid-extracting reagents because of its marked protective properties and its inertness toward the indicator. Trichloroacetic acid causes fading of the indicator, which may be very rapid with some batches.²⁹ Sulfuric acid reacts with the dye and should never be used.¹⁵ Tungstic acid³⁰ has been used in blood determinations and, although it is a more complete protein precipitant, lacks the protective characteristics of metaphosphoric acid.

An extract of a representative portion of the plant or animal tissue under examination (from 5 to 10 Gm.) is prepared by grinding in a small mortar with sand and fresh 3 per cent metaphosphoric acid until a thin paste is formed. The solids are thrown down in a centrifuge and the clear extract is decanted. Another portion of extracting liquid is used to wash the mortar and is stirred into the solids, which are again centrifuged. The rinsing and washing process is repeated, and the decanted aliquots of the extracts are diluted to 50 cc. Aliquots (10 cc.) of the extracts are titrated with the standard 2,6-dichlorophenolindophenol solution until a faint pink end point is reached. A 10 cc. microburet graduated in 0.01 cc. is convenient.

The indophenol reacts rapidly with vitamin C and should be dropped in at a brisk rate. The end point for most plant tissues is stable for twenty seconds or more, while animal tissues usually fade after from ten to fifteen seconds because of a slow reaction by other substances. Such extracts should be titrated only to an end point at which rapid fading ceases. A correction for the amount of dye required to bring 10 cc. of the extracting acid to the same end point should be applied to all determinations, including the standardizations. This quantity is greater than the usual indicator corrections and should never be neglected. The results are most conveniently expressed in terms of milligrams of ascorbic acid per hundred grams of fresh weight, but in studying vitamin C in tissues which vary considerably in water content, one may get a clearer picture by basing the analysis on dry weight.

Comment.—Since the indophenol method depends on the reduction of the reagent by vitamin C, many substances having a reducing potential lower than the dye are possible sources of interference. However, most such substances found in natural systems react with the

indicator at a perceptibly slower rate than ascorbic acid under the conditions of the titration. This is a requirement for the specificity and accuracy of the method. The end point with plant tissues is stable for some time, but many animal tissue extracts and urines contain sufficient amounts of slow-reducing substances to make the end point less distinct. This is especially true when small quantities of ascorbic acid are being titrated. In such cases the accuracy of the titration depends on the skill of the observer in detecting the point at which rapid reduction is replaced by a slow fading of the indicator. It is true that this feature limits the accuracy of the method, but the precision in most cases is still within the range of biologic variation. The errors are of about the same order as those for blood sugar tests. Unknown reducing materials are reported to interfere with the test in nerve tissue,³¹ eye lens and aqueous humor,³² the liver of some species³³ and tumor tissues.³⁴ Reduction by phenols, tannins, glutathione and many other substances is eliminated by titration in acid solutions below p_H 3. Cysteine, sometimes present in autolyzed tissue, must be estimated separately or removed from the system. Ergothioneine, thiosulfate, cysteine and other organic sulfur compounds may be removed by a rather impractical mercuric acetate treatment suggested by Emmerie.³⁵ Reductone (glucic acid),³⁶ reductic acid³⁷ and other derivatives formed in hot alkaline sugar solutions reduce the dye in a manner indistinguishable from that of vitamin C. Similar compounds are found in yeast, mold, malt extract and beer.³⁸ These examples illustrate the point that when one is dealing with a type of material not previously checked it is best to establish the validity of the test by other means.

Recent evidence^{38a} suggests that there may exist in certain plant tissues significant quantities of physiologically available combined ascorbic acid which is not extracted by the usual acid extracting reagents and therefore is not included in the titration value. Unless the extracts are carefully prepared and titrated without too much delay, oxidation of vitamin C by liberated enzymes or traces of metals may cause a low titration figure. If the oxidation has proceeded beyond the first step as previously indicated,³⁹ both the chemical and the biologic value will be low. In general, reversibly

oxidized ascorbic acid (dehydroascorbic acid) represents an insignificant portion of the total biologic value of fresh or storage products.

The titration value of some tissue extracts may be increased by preliminary treatment with hydrogen sulfide.³⁵ Some investigators have interpreted this increase as due to reduction of dehydroascorbic acid and have modified the method to include both forms of ascorbic acid. There is some doubt whether it is due to the reduction of dehydroascorbic acid or to the reduction of other substances which are then included in the titration. The uncertainty of the procedure is also increased by the necessity of completely removing the gas because hydrogen sulfide also reduces the indicator. Emmerie and Van Eekelen recommended the use of mercuric acetate to remove cysteine ergothioneine and of thiosulfate followed by treatment with hydrogen sulfide. The extra manipulation involved, with uncertainty at every step, makes the method at present of doubtful value.

Microtitration with indophenol for special purposes has been described by Birch, Harris and Ray,⁴⁰ Farmer and Abt⁴¹ and Glick.⁴² The last named has applied the Linderstrom technic to microtome-cut sections of glandular tissues with some success.

Other Chemical Methods.—Alternative methods based on the reduction of ferrocyanide,⁴³ phosphotungstic acid,⁴⁴ methylene blue⁴⁵ phosphomolybdic acid⁴⁶ and other color reagents have been proposed. From a theoretical standpoint it would seem that these reagents might be as specific and useful as indophenol, but for one reason or another they have not been widely adopted. In some cases they react too slowly in acid solutions (p_H from 2 to 3 is a necessary condition for specificity). The color changes often vary with time. Many of these reagents react quantitatively with pure ascorbic acid solution but are inhibited or reduced by other materials in urine and tissue extracts. Ascorbic acid in some cases shows side reactions with the reagent, thus interfering with quantitative reduction. A spectroscopic method⁴⁷ in which the intensity of absorption (265 millimicrons) is measured before and after the destruction of the vitamin has been of value in checking the accuracy of the indophenol method. Extracts require special attention in removing irrelevant absorbing materials. Tauber and Kleiner⁴⁸ advocated the determination of reducing capacity before and after the destruction of the vitamin by an oxidase as a means of increasing the specificity of the test. This method is also not entirely specific, because of the nonspecificity of the

enzyme.⁴⁹ Roe⁵⁰ has described a method based on another principle, the color reaction between aniline acetate and furfural, a decomposition product of ascorbic acid.

In general the special features of these procedures are outweighed by features which make them less straightforward and less specific than the indophenol method. A discussion of the weaknesses and merits of all the proposed chemical methods is not within the realm of this paper.

Urine Technic.⁵¹—The excretion of vitamin C in the urine depends primarily on the relative degree of saturation of the tissues and the immediate intake of ascorbic acid. As a state of tissue saturation is approached, the quantity of ascorbic acid excreted in the urine gradually increases until at saturation a marked abrupt elevation occurs. The quantity of ascorbic acid required to induce saturation appears to be a measure of the state of vitamin C nutrition of the patient.⁵²

The analytic procedure for urine is essentially the same as that previously described for tissues. Each specimen of voided urine is measured and a 50 cc. volume containing 10 cc. of 20 per cent metaphosphoric acid is filled to the mark and stoppered. Aliquots should be stored in the refrigerator and titrated within eight to ten hours, during which time relatively little loss occurs. For analysis, the specimen is centrifuged if cloudy, and from 2 to 5 cc., depending on the concentration of ascorbic acid, is diluted to 10 cc. with 3 per cent metaphosphoric acid. The mixture is quickly titrated to a definite pink end point against a standard indophenol solution, a microburet being used. After correction for the titration blank and the added metaphosphoric acid, the total excretion of the specimen is estimated and the twenty-four hour output calculated. The reducing capacity of the urine collected during a preliminary period before the test establishes the excretion level of the patient before treatment with ascorbic acid. This also places the interpretation of the test on a comparative basis, thus correcting for the small constant effect of reducing substances other than ascorbic acid usually present in the urine.⁵³ Heinemann⁵³ has reported a significant interference by thiosulfate, especially when the diet is high in protein. However, the virtual disappearance of the reducing value in cases of scurvy and extreme deficiency and its restoration at a predicted rate when ascorbic acid is fed contribute strong evidence for the accuracy of the test. Provided manipulations are carried out properly and interpretations of too fine a character are not attempted, the method is of real value.

The estimation of the excretion of ascorbic acid before and after a single dose is also of value in demonstrating the presence of subnutrition of vitamin C. This procedure undoubtedly shows the absence of saturation, but sufficient data have not been collected to allow for an estimation of the degree of deficiency such as is possible by the repeated dose method.

Blood Technic.⁵⁴—The vitamin C level of normal blood plasma as estimated by titration shows a close correlation with the level of intake, thus providing means for evaluating the reserve vitamin C by a single determination for persons in that wide zone between scurvy and saturation (from 0.3 to 1.8 mg. per hundred cubic centimeters). This rapid direct application of the test will undoubtedly replace the less practical urine technic for many purposes.

With slight variations, the procedure now most widely used for blood titrations is as follows: Five or more cubic centimeters of blood is oxalated in a tube which also contains 2 mg. of potassium cyanide, and 2 cc. of plasma is pipetted into 8 cc. of 3 per cent metaphosphoric acid solution. The mixture is stirred, stoppered and centrifuged. A 5 cc. aliquot (equal to 1 cc. of plasma) of the clear centrifugate is immediately titrated, as previously described, with dilute 2,6-dichlorophenolindophenol. After a correction for the blank, which always should be performed parallel with a determination, the ascorbic acid is calculated and expressed as milligrams per hundred cubic centimeters of plasma. All sources of error being taken into consideration, the titration is probably within 0.1 to 0.2 mg. of the true ascorbic acid content of the blood for the range from 0.3 to 1.8 mg. per hundred cubic centimeters. With plasma of lower value, the errors are greater. Cyanide is added to inhibit the slow inactivation of ascorbic acid which occurs in both plasma and filtrate. This is a good precautionary measure against oxidation due to traces of copper and other catalysts, although I have never observed such high rates of destruction in the absence of cyanide as have been reported.⁵⁵ With carefully prepared reagents and water redistilled from glass, the filtrates remain stable for several hours. Metaphosphoric acid is preferred as a deproteinizing agent for reasons previously stated. Plasma is preferred to whole blood for vitamin C determinations because of the greater stability of plasma filtrates.⁵⁶ Substances liberated from red cells by deproteinizing reagents catalyze the inactivation of ascorbic acid even in the presence of cyanide. For this reason plasma which shows evidence of hemolysis is unsuitable for ascorbic acid determinations. Another objection to using whole blood filtrates for vitamin C titration arises from liberation of substances that also reduce the dye. This becomes especially significant when the filtrate is treated with hydrogen sulfide before titration, as recommended by some investigators.

A satisfactory method requiring less blood would be of distinct value in preventing the necessity of venous puncture. Micromethods so far published have not been a solution to this problem. The chief difficulty of titrating such small quantities lies with the inaccuracies of the end point determinations. Mindlin and Butler,⁵⁷ in an unpublished manuscript, propose a method which yields results satisfactory for clinical purposes by the use of from 0.2 to 0.3 cc. of capillary blood. The decrease in concentration of colored indicator produced by the addition of an amount of blood plasma filtrate insufficient to cause complete reduction of the dye is

measured by means of a photo-electric colorimeter. This eliminates the subjective reading of the end point. An accurately standardized dye is not needed. Observation of the rate of fading of the color with time permits the detection and study of reducing substances reacting at a slower rate than ascorbic acid.

It is important to emphasize the fact that titrations of blood and many other tissues which are extremely low in ascorbic acid have a limited accuracy even when done with the greatest care. A disregard for this fact is apparent from published investigations. Conclusions based on differences far smaller than the errors of the method used are obviously of doubtful value. Such misinterpretation can be avoided only by a thorough understanding and proper application of the technic.

DIETARY SOURCES

This discussion is concerned with the distribution of vitamin C in food and necessarily lays emphasis on this subject. It should be remembered that adequate nutrition is a problem of supplying many factors in proper proportions and can be met only by use of a variety of foods. Condemnation of a food product because it possesses a low vitamin C value, unless this is a consequence of improper processing or handling, is unjustified. Some foods with many excellent nutritional properties are naturally of low antiscorbutic value.

Ascorbic acid value as far as nutrition is concerned is dependent primarily on two factors: (1) the natural potency of the particular plant or animal tissue and (2) the consequence of aging and processing which occurs before its use as food.

Among the richest sources of vitamin C are oranges, lemons, grapefruit (raw or canned), tangerines, tomatoes (raw or canned) fresh strawberries, green peppers and raw cabbage.⁵⁸

Properly prepared green leafy vegetables have good vitamin C value in spite of the relatively large losses from cooking or canning. In this group may be classed cabbage, spinach, brussels sprouts, kale, broccoli and vegetable greens, such as turnip, beet and dandelion.

Apples, bananas, pineapples (canned), potatoes, green beans and green peas, although containing less antiscorbutic activity, are important sources because of the quantities included in the diet.

The lettuce group, including escarole, have a lower vitamin C content than is generally realized but, since they are usually consumed raw, compare favorably with cooked vegetables. Other important vitamin C-containing foods are kohlrabi, onions, turnips, parsnips and cauliflower.

Dry cereals and legumes of all varieties are devoid of vitamin C, but almost any seed soaked in water for twenty-four hours and kept moist for a few days until it sprouts becomes an effective antiscorbutic substance even when cooked. The British committee on accessory food factors has recommended the use of sprouting seeds as antiscorbutic foods in times of famine.

Cooked muscle meat² is practically free from ascorbic acid, although experience seems to show that if consumed rare or raw in large quantities it prevents scurvy. Liver is greatly superior to muscle in this respect. The distribution of vitamin C in other animal tissues (not important as food) has been discussed in a previous paper of this series.⁵⁹

Butter, eggs and cheese contain no vitamin C. The vitamin C value of commercial pasteurized milk is very small.

*Variety.*⁶⁰—Before the introduction of the chemical method, it was not practical to undertake any comprehensive study of the influence of various factors such as variety, type of soil, season and maturity on the vitamin C potency of fruits and vegetables. Enough information has been obtained now to indicate clearly the need of attention to these points in attempting to obtain food of the highest antiscorbutic value.

Certain varieties of tomatoes⁶¹ contain double the quantity of vitamin C of others grown on the same soil under the same conditions. Cannors of tomato juice should give as much attention to this fact as to methods of processing in order to provide the most potent product. Some varieties of apples⁶² are definitely higher in antiscorbutic value than other varieties. Similar consistent differences according to variety have been reported for spinach,⁶³ cabbage,⁶⁴ beans and peas⁶⁵ and probably exist for most fruits and vegetables.

Soil conditions affect the vitamin C content of spinach. Several varieties grown on upland soil were found to average 50 per cent richer than the same varieties grown on muck soil when compared under otherwise similar conditions.⁶⁶ Fall spinach when compared with the same varieties grown in the spring was found to be appreciably higher in ascorbic acid content. It therefore seems likely that crops from year to year may vary in ascorbic acid value because of conditions such as moisture and temperature.

Maturity and Origin.—Tomatoes increase somewhat in vitamin C content as the fruit ripens.⁶⁷ However, mature green tomatoes may have nearly the same value as the red ripe fruit.⁶⁸ The ascorbic acid content of green peppers increases considerably on reddening. A single fruit which is green on one side and red on the other may show a difference of as much as 75 per cent.⁶⁹ A lower vitamin C content in oranges sprayed with lead arsenate has been reported.⁷⁰ Immature Bramley seedling apples are as rich in vitamin C as mature fruit.⁶⁸ Most green leafy and root vegetables contain the greatest concentration of vitamin C during the period of most rapid growth. Sweet corn⁷¹ and green peas⁷² show a maximum vitamin C content during the tender stage, and the content decreases as the seed matures. This is consistent with the lack of vitamin C in nonrespiring mature seeds. Ethylene ripening itself has no effect but tends to encourage early picking and may lead to a slightly lower vitamin C value due to immaturity.⁷³

How and from what most plants and some animals form ascorbic acid is not clear, but the distribution in animal tissues shows it to occur in the greatest concentration in the most actively functioning tissues, in the

adrenal cortex, corpus luteum, thyroid, pituitary body and liver. This distribution proves to be true also in leaves and growing shoots and suggests a fundamental concern with respiratory processes. However, many rapidly growing fruits are low in ascorbic acid, and the respiratory activity of lemons, oranges and tomatoes does not seem to be unusually high, although these are among the richest sources of ascorbic acid. Eggs and seeds are devoid of vitamin C, but the vitamin forms immediately from unknown constituents when a chick embryo develops or the seed sprouts.

Storage.⁶⁸—Time, temperature, care in handling and type of product are important factors in the problem of the stability of vitamin C during storage. Spinach which has stood for a few days at room temperature and has become wilted loses about one half of its ascorbic acid, while the same spinach kept at 37 or 38 F. for the same period retains its original value.⁷⁴ This is true in general of green leafy vegetables of this type. Cabbage stored at room temperature loses about 25 per cent of its vitamin C in a month, while at 45 or 50 F. the loss is only 10 per cent.⁶⁴ Green beans and peas, like spinach, rapidly lose their ascorbic acid at room temperature but keep well by refrigeration.⁷⁵ Sweet corn in the husk retains its vitamin C well for two or three days, after which time a slow loss occurs.⁶⁸ Green peppers remain rich sources of ascorbic acid for several weeks if they do not become bruised or wilted.¹⁵ Loss in apples after three months at 45 F. approximates 15 per cent, at six months 25 per cent and at one year 50 per cent.⁷⁶ Lemons and oranges stored at 45 or 50 F. for ten months show losses of from 10 to 30 per cent; no detectable loss occurs in two months.¹⁵ Storage of ripe tomatoes at ordinary temperature for a month causes little change in the vitamin C content provided the fruit remains firm and free from bruises and rot.⁷⁷ Potatoes very slowly lose their vitamin C under market conditions; about a 50 per cent loss occurs in one year.²² With some varieties, little loss is observed after from three to six months' storage.⁷⁸ Vitamin C in rutabagas, carrots, turnips and sweet potatoes is slowly lost over a period of several months.⁶⁸

These facts demonstrate the great variation in "storage stability" of vitamin C and indicate the advantage of cold storage as compared with ordinary storage.

Freezing.—Preservation of fruits and vegetables by quick freezing has become an important commercial method.⁷⁹ Studies on the stability of vitamin C during freezing and storage in general have shown slight destruction, but often incidental processing operations such as shelling, washing and blanching lead to significant losses. Asparagus, apples, potatoes, strawberries, blackberries and orange juice are unaffected by freezing, while some losses are reported in preparatory operation with peas, beans and spinach. Freezing results in a certain amount of cellular disorganization, with liberation of enzymes from some types of plant tissues. Unless these products are properly blanched (to destroy enzymes) before freezing, considerable losses may occur during storage and thawing. Slow-thawing vegetables

rapidly lost their vitamin C. Losses of from 80 to 90 per cent may occur in beans, peas or spinach in a few hours. Frozen foods should not be defrosted until ready to cook or serve raw. Losses are reduced to a minimum by cooking without preliminary defrosting.

Processing.—For several reasons, effort should be made to conserve the vitamin C values of the general food supply rather than to depend on the use of foods of special antiscorbutic properties. A larger percentage of the people than is generally realized, because of economic conditions, lack of knowledge or poor food habits, do not include citrus fruits, tomatoes or other richly antiscorbutic foods in their diet. These people necessarily depend on the general food supply for their source of this essential. Also the loss of important food qualities, such as flavor and the content of other vitamins, usually parallels the destruction of vitamin C. In fact, the preservation of ascorbic acid may well be used as a general index to the care with which certain foods have been processed.

The preservation of vitamin C between harvesting and consumption is essentially a problem of combating oxidation, a process dependent on time and the kind and state of the tissue and influenced by temperature, access to air and presence of metals and enzymes. The destruction of vitamin C when tomato juice is heated can be reduced two thirds by rendering the conditions anaerobic.⁸⁰ Spinach and cabbage cooked by methods excluding air are from 50 to 100 per cent richer in vitamin C than when prepared by open kettle cooking.⁸¹ The water in which vegetables are cooked may contain sufficient oxygen to become an important factor of destruction.⁸² This fact has led to the practice of starting vegetables in hot water.

Crushing or bruising of many vegetables such as spinach, cabbage, turnips and rutabagas causes the liberation of enzymes (oxidases) which in the presence of air catalyze the oxidation of ascorbic acid.²⁶ This is a rapid reaction and may lead to complete inactivation of the injured tissue in a few minutes. Starting the cooking in hot water quickly inactivates these enzymes. Shredded carrots, cabbage and other roots and leafy tissues rapidly decrease in vitamin C content and should therefore be prepared fresh before serving.

Vitamin C is more stable in an acid medium than in a neutral or slightly alkaline medium.⁸³ The addition of soda to cooking vegetables may produce a better color but will lead to increased loss of vitamin C. The vitamin C in tomato juice is naturally stable but becomes rapidly inactivated when neutralized or made alkaline with soda. In general, vitamin C is less subject to oxidation in those fruits and vegetables which are acid.

There is perhaps no single factor which accelerates the destruction of vitamin C so much as copper salts. The presence of air and the merest traces of copper lead to complete inactivation often in a few minutes. Contact with bare copper or utensils made of metal containing copper must be avoided. Quantities of copper so small as to be undetectable by the usual chemical methods will lead to immediate and complete destruction of the ascorbic acid in raw milk or cooking vegetables.⁸⁴ The insidious nature of this factor makes it

very difficult to control, for, in addition to contamination by contact and from the water supply, many foods naturally contain enough copper to be active.

Drying⁸⁵ in itself is not detrimental to vitamin C, but for most foods it is almost impossible to prevent oxidation due to other factors sufficiently to prepare dehydrated products of important and lasting antiscorbutic values. Dehydrated foods have repeatedly failed in this respect when used in times of war. Many experiments have been reported showing that certain of the more acid fruits may be prepared so as to conserve a reasonable degree of their vitamin C activity, but commercial products cannot as yet be considered dependable in this respect.

agreement with the previous emphasis on the unfavorable "influence" of contact with copper utensils, access to air, prolonged heating and alkalinity. Modern commercial canning, with careful plant control, can prepare products with a minimum loss of vitamin C which are comparable to carefully cooked fresh food. However, no rule can cover all cases, for there are badly controlled canneries as well as bad cooks. The variations in processing are so great that the products from each process and perhaps each batch would have to be tested before one could be sure of the vitamin C value. Boiling of cabbage in an open kettle or cooking in a pressure cooker leads to almost complete destruction, while starting the cabbage in boiling water and testing both the

* Unless otherwise indicated, these values are on fresh foods.

Pickling, salting, curing or fermenting usually results in complete loss of vitamin C. Fresh cucumbers contain from 5 to 8 mg. per hundred grams; salt pickles contain none. Fermented cider and other fruit juices are free from vitamin C. Sauerkraut and sauerkraut juice are unreliable antiscorbutic foods.⁸⁶ Commercial orange drinks which do not contain freshly prepared orange juice are practically free from ascorbic acid.⁸⁷ Vegetable juices rapidly lose their vitamin C because of active enzymes and a high p_H and therefore are usually poor antiscorbutic foods.

It is difficult to make general statements concerning the loss of vitamin C during such a variable process as cooking⁸⁸ or canning. Recent work is in essential

cooking water and the cabbage produce about 25 per cent destruction and 25 per cent loss in the water.⁶¹ Similar studies on spinach, turnip greens and green peas and beans lead to approximately the same conclusions. Commercial canning destroys from 50 to 85 per cent of the vitamin C in peas, lima beans, spinach and asparagus. Home-canned tomato juice is as satisfactory as commercial canned juice, and both are good antiscorbutic substances.² Vitamin C is stabilized by acid and therefore suffers less destruction during cooking in acid fruits and vegetables. Canned grapefruit and orange juice are about 70 to 90 per cent as potent as the fresh juice and, like most canned products, remain stable while canned but slowly lose their vitamin C when left open to the air.⁸⁷ Baked and boiled potatoes are reported to show only small losses unless overcooked.⁸⁹ Fruit jel-

lies and jams are usually low in vitamin C. Warmed over foods are practically free from ascorbic acid. Canned or cooked apricots, peaches, plums and cherries are practically free from vitamin C. Freshly prepared apple sauce or apple pies retain from 20 to 30 per cent of the original vitamin C value of the apple.⁹⁸

The use of canned sieved vegetables and fruit for children has increased at a rapid rate in the last few years.⁹⁹ In spite of the most careful methods of processing, partial destruction of vitamin C is unavoidable. A great deal of variation in this occurs, depending on the type of food, freshness and method of processing, but in general it has been shown that the loss of vitamin C is slightly greater for purées than for the corresponding canned whole vegetables. As a rule these products cannot be classed as potent antiscorbutic foods, although they may contribute materially to the diet because of the quantity consumed.

Milk is the most nearly perfect and the least dispensable food. Nevertheless, the vitamin C content of commercial milk, raw or pasteurized, is not dependable and should never be relied on to supply the requirements. The use of the titration method has led to a better understanding of those factors which may influence the vitamin C content of milk, such as aging, pasteurization and handling. Judging from a large number of determinations, both biologic and chemical, one may expect from 2 to 2.5 mg. per hundred cubic centimeters of ascorbic acid in fresh raw milk.⁹¹ Even when the milk is cold this value slowly decreases, until a loss of from 20 to 30 per cent may occur in twenty-four hours. Sunlight or traces of copper accelerate this change.⁹² Pasteurization by the widely used holding method, unless unusual precautions are observed, results in a loss of from 30 to 60 per cent. However, pasteurization by the short time high temperature process with absence of copper leads to slight inactivation.⁹³ Loss of vitamin C activity due to pasteurization, aging, reheating and diluting, such as usually occurs in preparing a formula for babies, results in a formula of very low antiscorbutic value.¹⁵

Although Hess⁹⁴ found that a pint of milk a day prevented infantile scurvy, the commercial milk of today, which contains from 0.3 to 1 mg. per hundred cubic centimeters, is a rather poor source of vitamin C. The 5 mg. of ascorbic acid represented by a pint of average commercial milk is far below that recommended for optimum nutrition. This fact has led to the general use of orange juice, tomato juice or potent antiscorbutic substances as a supplement to the infant diet. A breast-fed infant of a normally nourished mother receives from 20 to 40 mg. of ascorbic acid daily from the day of birth, because human milk is from four to six times richer in vitamin C than cow's or goat's milk.⁹⁵ The implication is strong that vitamin C should be a constituent of the infant's diet at a very early age.

The ascorbic acid value of canned or dried milk depends primarily on the method by which the milk is prepared or handled. Commercially evaporated milk which has been sterilized at a high temperature is almost free from vitamin C, while sweetened condensed milk which has been evaporated in vacuum at lower temperatures retains a proportion of vitamin C comparable to that of pasteurized milk. Several investigators have reported good conservation in dried milk.⁹⁵ However, most commercial preparations are practically free from vitamin C.¹⁵

The vitamin C concentrations of individual foods are summarized in the accompanying table. Most of the analyses reported were on fresh material. It is difficult to estimate values for cooked or processed food because of the lack of uniformity of methods and treatment. Lower vitamin C values than those given must be expected because of immaturity, lack of freshness, poor preservation, long storage or results of processing. The figures given are estimates derived after consideration of the available data,⁹⁶ including the results of many unpublished analyses from my own laboratory, and represent my judgment of the expected value of the raw edible portions under good market conditions. The value when the food is ready for serving will depend on the method of preparation. A recent United States Department of Agriculture bulletin⁴ contains fuller details of the vitamin C contents of foods and also references to the literature.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE.

HOWARD A. CARTER, Secretary.

AIR FILTRATION

TELL NELSON, M.D.

CHICAGO

By air filtration is implied the removal of impurities, usually in the form of dust, from the air. The benefits derived from such treatment of the air are of great importance in industry as well as in the control of many respiratory diseases.

It can be stated that no air is free from dust. Dust comes from almost every process in which there is disintegration of materials and is thrown into the air by any method that will disturb the dust. Once the particles are in the air, they will remain suspended for varying periods of time, from a few seconds to years, depending on their size and density. Particles of dust differ in size from those which can be seen only by an ultramicroscope to those which are easily discerned by the naked eye, particles 10 microns in size or larger. However, the particles of most concern in their effect on the human body are those from 0.5 to 100 microns in size.

The concentration of dust particles in the air varies greatly, depending on the conditions operative in the locality where samples are taken. In country air which is comparatively clean, especially after a rain, the particles may be as low as a few thousand per cubic foot

of air, whereas city air will contain from five hundred thousand to two or three million particles per cubic foot. In heavy industrial centers the contamination has run as high as twenty million particles per cubic foot. Recent studies bear out previous observations of air pollution in both urban and rural areas.¹ In many industries the dust level is tremendous.

The normal concentration of permanent dust in the air is not of much concern, as it actually serves a useful purpose in reflecting light and forming nuclei for rain drops. There are, however, great objections to certain kinds of dust and to their heavy concentrations. In addition to the economic loss due to dust, the effect either direct or indirect on health is often of vital importance.² If the concentration is of sufficient magnitude, ultraviolet rays may be shut off.³ Dust as nuclei for fine droplets of water may form fog in heavy industrial areas.

The direct effect of dusts on health depends to a large extent on their chemical composition and the size of the particles. In many industries dusts and fumes are liberated in sufficient quantities to be injurious to the health of the workers. Many such dusts are direct poisons, as arsenic, lead, mercury, manganese and cadmium. Lead poisoning is a classic example of a disease due to such an occupational hazard. Inhalation of other solid and gaseous ingredients of city air, such as carbon and sulfur fumes, irritates the mucous membranes of the nose, throat and lungs, producing discomfort, and in some instances it may cause injury to health.⁴ In addition, the inhalation over long periods of fine inorganic dusts, such as silicates, iron, carbon and asbestos, leads to the fibroid condition of the lungs known as pneumoconiosis. These particles are probably smaller than 1 micron and when lodged in the alveoli of the lung produce a low-grade inflammatory reaction and the appearance of dust carrying phagocytes. Passing into the lymphatics, the dust cells tend to migrate along the lymphatics to the hilar nodes. If present in excessive amounts, they block lymph flow, with resulting localized lymphoid hyperplasia and fibrosis.⁵

In persons who are sensitized to pollens, inhalation of these air impurities precipitates symptoms of hay fever and pollen asthma. The concentration of pollen in the air varies greatly in different localities and is often enormous. In Chicago, for example, it has been shown that hundreds of tons of ragweed pollen are liberated each season.⁶

Many mechanical devices have been built for removing dusts from the air. However, because of the large variety of dusts, their difference in size and chemical composition and the varying conditions under which they are found, there is no single filtration method which is applicable to all.

The main object is to remove as nearly 100 per cent of the dust as is possible. To this end Rowley⁷ has

laid down a group of fundamental requirements for air filtering devices, namely:

1. High efficiency, or dust arresting power.
2. Low resistance to the flow of air through the filter.
3. High dust-holding capacity, or long life in service.
4. Economy in first cost and upkeep.
5. Freedom from odors.
6. Fire resistance.
7. Uniform efficiency over a wide range of air temperature.
8. Low moisture absorption.

Obviously these requirements must be modified to fit certain types of air cleaning, such as the water spray.

Air cleansing may be accomplished in numerous ways. In general the methods can be roughly grouped into five main divisions: air washers (water sprays), dry filters, viscous coated filters, electrical precipitators and dynamic precipitators.

The results obtained from any specific type of filtering method depend on specific properties of the filtering device and the operating conditions under which it is used and will vary over a wide range. Each method has a definite field of usefulness and when used within its own limitations attains its maximum efficiency.

In general it may be stated that dusts of small size which are harmful to health require filtration of the highest efficiency under the most variable conditions. In industry, the dynamic and electrical precipitators are perhaps the most efficient for the removal of the smaller particles of dust, whereas for home and hospital use dry filters are most efficient.

The air washer for the removal of dust and pollen from air does not have as high a degree of efficiency as other methods. Mechanically it is impossible to remove all fine dust particles from a stream of air with an air washer. Bubbling air through a volume of water at a slow rate, particularly if the water is greatly agitated by mechanical means, gives a higher degree of efficiency in dust removal than the air washer. The greatest field of usefulness of the air washer is as a primary cleaner in a system in which there is a secondary filter of greater efficiency. In this capacity it will remove the larger particles and thus give a longer life to the secondary filter in addition to maintaining or increasing the humidity.

Dry filters are made from felt, closely woven cloth, cotton mats and cellulose material (paper type). A filter of this type is spread on a frame, usually in a fluted fashion to give a large filtering surface to allow a slow seepage of air. Modern developments in this type of filtering medium permit large volumes of air to be passed through the filter without sacrificing efficiency. It is apparent that this type of filtering material is superior to water cleaning as well as viscous coated filters for the removal of dusts and pollens injurious to health. Such filters are well adapted for installation in hospitals and homes where filtration is required. Their efficiency is at its maximum when the filter is new. When properly cared for under ordinary operating conditions, the loss in efficiency of dry filters is very slight.

Viscous coated filters are made of numerous types of materials such as spun glass, metal wool or fibrous material, which are usually packed loosely in a frame or so arranged that the air is deflected from surface to surface. The material is coated with a thick viscid oil. The retention of dust is due to the fact that it sticks

to the oily surfaces and not that particles cannot pass through the openings. This type of filter has its lowest efficiency for dust arrestment when new, but as the filter fills with dust the efficiency increases.⁷

Electrical precipitators have lately been advocated for use in the removal of dust and pollen from the air. They maintain a high degree of efficiency for dust removal. The operating principle is not new in industry, where it is known as the Cottrell method. It consists of suspending a wire at a high potential below a series of plates which are oppositely charged. The dust particles are charged by the high potential wire and in passing over the plates are electrically attracted to them and stick there. This method is efficient for particles smaller than 0.5 micron. Its disadvantages for home and hospital use are that it may liberate ozone, which at times may produce secondary effects, and it requires constant operation to maintain its efficiency. If the unit is shut down, the particles which have become adherent to the plates lose their charge and may fall to the bottom of the ducts, and when operation of the unit is resumed these may be blown out in a large volume. The electrical filtering device therefore requires a supplementary filter when used in homes or hospitals. A filter to be used in homes or hospitals should be as foolproof as possible.

Dynamic precipitators usually combine an exhaustor and dust collector in a single unit. There is a primary and secondary air passage and a turbine-like impeller composed of a large number of carefully calculated hyperboloid blades. The dust laden air is drawn into the unit by forces created by the rotating impeller; then the dust is separated and the cleaned air discharged. Dust drawn off by the impeller is directed through the secondary air circuit and collected in a hopper or passed outdoors. The dynamic precipitator has a very high degree of efficiency for dust removal as the result of the magnitude of the centrifugal and dynamic forces imparted to the dust particles by the impeller.

Within the past ten years, filtration of air for the removal of particulate matter has received a great deal of attention from the medical profession.⁸ This has been particularly true in the field of allergy. Its usefulness in the relief of symptoms of hay fever and pollen asthma and in other inhalant allergies as well as its value as an aid in diagnosis has been amply demonstrated.⁹ A brief survey of its value as shown by numerous workers may be summarized as follows: In uncomplicated hay

fever, residence of the patient in adequately filtered air will prevent the onset of symptoms due to sensitivity to pollens. Symptoms appear as soon as the person is exposed to pollen laden air. Persons experiencing symptoms due to pollen are relieved on entering a room with adequately filtered air, the length of time required for such relief depending on the severity of symptoms on entering. In a large series of observations, the average time required for maximum relief was found to be 1.2 hours.¹⁰ Residence in dust and pollen free air does not increase a person's resistance to pollen or dust, nor is it a cure for pollinosis or dust sensitivity.

Pollen asthma likewise will be relieved by residence in adequately filtered air, the length of time required for such relief varying greatly with the severity of the asthma and the duration of the attack. This time may vary from a few hours to several days or even weeks.¹¹ The subjective symptoms clear up more rapidly than do the objective symptoms. Persons who have pollen asthma remain free as long as they remain in filtered air, with certain exceptions. As has been shown,¹² atmospheric changes of wide amplitude may precipitate severe symptoms in persons with pollen asthma confined in adequately filtered air. However, the patients must first have been exposed to pollen. Other factors of air conditioning such as controlled humidity and temperature play a definite role in the relief of pollen asthma. It has been observed that the rapidity with which persons who have pollen asthma are relieved is greater under conditions of low humidity and relatively constant temperature in pollen free atmosphere than when the temperature and humidity are not controlled.¹³ In such controlled atmospheres, attacks of asthma precipitated by storms were apparently delayed from six to eight hours and were less severe than those observed when humidity and temperature were not controlled.¹³

Residence in adequately filtered air is a procedure of great help in the diagnosis of allergic conditions. The effect of dusts, pollens and other inhalant factors usually may be ruled out in a few days by this method.

In other respiratory conditions which are definitely attributed to the effect of dust such as pneumoconiosis, the use of air filtration for removal of dusts is now a recognized preventive measure. Many industries, realizing the benefits derived by the employees from such treatment of the air, have installed devices for the removal of dust.¹⁴

Air conditioning is recognized as most essential in many manufacturing processes, as for example in the production of rayon, photographic film, capsules, candy,

chemicals, flour, textiles, linoleum, watches, safety glass, powdered milk, tobacco products, fine printing and lithography, and in many laboratories. The control of air-borne fungi and molds in such industries as brewing has been greatly aided by the use of air filtration. In most of these industries, air cleanliness is of equal importance to the control of humidity and temperature and forms a most essential part of the air conditioning mechanism.

The progress made in the field of air filtration within the past few years has been a great help in both industry and medicine. The deleterious effect of dusts on health is now a well recognized fact and the removal of dust particles has definitely been established as beneficial. Further application of the principles of air filtration to other fields of medicine and industry will result in greater perfection of filtration appliances with a higher degree of efficiency.

636 Church Street, Evanston, Ill.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

ANTIMENINGOCOCCIC SERUM (See New and Non-official Remedies, 1937, p. 395).

The Gilliland Laboratories, Inc., Marietta, Pa.

Antimeningococcic Serum, Concentrated and Refined—Gilliland.—Serum which has been refined and the antibodies so concentrated that 10 cc. is equal to at least 40 cc. of the whole (unrefined) serum. The concentrated serum is equivalent in activity to several times the quantity of unconcentrated serum. The concentrated serum is desirable for intravenous administration, since much of the inert protein has been removed, and for intraspinal administration where often it is possible to withdraw only small amounts of spinal fluid, as in children. The serum is tested for its precipitin and agglutinin content in mice and is standardized according to the requirements of the National Institute of Health. Marketed in packages of one 10 cc. double end vial and in packages of one 10 cc. double end vial with sterile intraspinal needle and improved gravity injecting outfit. A vial of a 1:10 dilution of this serum is included with each package for determining the sensitivity of the patient.

Dosage.—The usual intraspinal dose for adults and children is 10 to 20 cc., repeated every twenty-four hours until at least two successive specimens of fluid show no organisms by bacteriologic examination. It is necessary to exercise more than ordinary care in removing fluid and injecting serum in babies. In addition to the intraspinal dose, 5 cc. for children and 20 cc. for adults may be administered intravenously in very early cases or in those cases accompanied by frank meningococcemia as demonstrated by positive blood cultures.

NICOTINIC ACID (See THE JOURNAL, July 2, 1938, p. 27).

Tablets Nicotinic Acid, 50 mg.

Prepared by John Wyeth & Brother, Inc., Philadelphia.

Tablets Nicotinic Acid, 100 mg.

Prepared by John Wyeth & Brother, Inc., Philadelphia.

SULFANILAMIDE-ABBOTT (See THE JOURNAL, March 12, 1938, p. 815).

The following dosage form has been accepted:

Sulfanilamide-Abbott, 1 Gm. Ampoules (Crystals).

McKESSON'S COD LIVER OIL CONCENTRATE IN OIL, 6 CC.—A concentrate of the nonsaponifiable fraction of cod liver oil adjusted to a potency, by dilution with corn oil, of 58,800 units (U. S. P.) of vitamin A per gram and not less than 5,880 units (U. S. P.) of vitamin D per gram.

Actions and Uses.—It possesses the therapeutic properties recognized for the vitamins present in cod liver oil.

Dosage.—Prophylactic, for infants and children 6 to 9 drops daily, or as prescribed by the physician.

Manufactured by the International Vitamin Corporation, New York (McKesson & Robbins, Inc., Bridgeport, Conn., distributor). The vitamin D concentrate used is made under U. S. patent No. 1,690,091.

ESTRONE (THEELIN) (See THE JOURNAL, Aug. 27, 1938, p. 784).

Estrone-Abbott.—A brand of estrone (theelin)—N. N. R.

Manufactured by the Abbott Laboratories, North Chicago, Ill., by license from St. Louis University under U. S. patents 1,967,350 and 1,967,351 (July 24, 1934; expire 1951). No U. S. trademark.

Ampoules Estrone, 0.1 mg. in oil, 1 cc.: Each cubic centimeter contains estrone 0.1 mg. (1,000 international units) in sesame oil.

Ampoules Estrone, 0.2 mg. in oil, 1 cc.: Each cubic centimeter contains estrone 0.2 mg. (2,000 international units) in sesame oil.

Ampoules Estrone, 1 mg. in oil, 1 cc.: Each cubic centimeter contains estrone 1 mg. (10,000 international units) in sesame oil.

Vaginal Suppositories Estrone, 0.02 mg.: Each suppository contains estrone 0.02 mg. (200 international units) in a glycerogelatin base.

Vaginal Suppositories Estrone, 0.2 mg.: Each suppository contains 0.2 mg. (2,000 international units) in a glycerogelatin base.

ESTRIOL (THEEOL) (See THE JOURNAL, Aug. 27, 1938, p. 784).

Estriol-Abbott.—A brand of estriol (theolol)—N. N. R.

Manufactured by the Abbott Laboratories, North Chicago, Ill., by license from St. Louis University under U. S. patents 1,967,350 and 1,967,351 (July 24, 1934; expire 1951). No U. S. trademark.

Capsules Estriol 0.06 mg.: Each capsule contains estriol 0.06 mg. diluted with milk sugar.

Capsules Estriol 0.12 mg.: Each capsule contains estriol 0.12 mg. diluted with milk sugar.

DIGITALIS (See New and Nonofficial Remedies, 1938, p. 186).

Pulvoids Digitalis Folium, ½ grain: Each pulvoid (compressed powder in tablet form) represents one-third cat unit.

Prepared by the Drug Products Company, Inc., Long Island City, N. Y.

Pulvoids Digitalis Folium, ¾ grain: Each pulvoid (compressed powder in tablet form) represents one-half cat unit.

Prepared by the Drug Products Company, Inc., Long Island City, N. Y.

Pulvoids Digitalis Folium, 1½ grains: Each pulvoid (compressed powder in tablet form) represents 1 cat unit.

Prepared by the Drug Products Company, Inc., Long Island City, N. Y.

DIPHThERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1938, p. 417).

Jensen-Salsbery Laboratories, Inc., Kansas City, Mo.

Diphtheria Toxoid, Alum Precipitated (Refined).—Also marketed in packages of one 10 cc. vial (ten immunizations).

PROPADRINE HYDROCHLORIDE-SHARP & DOHME (See New and Nonofficial Remedies, 1938, p. 237).

The following dosage forms have been accepted:

Propadrine Hydrochloride Capsules, ¾ grain.

Propadrine Hydrochloride Solution 3%: An aqueous solution containing 3 per cent propadrine hydrochloride and 0.5 per cent chlorbutanol as a preservative.

TETANUS TOXOID, ALUM PRECIPITATED (See New and Nonofficial Remedies, 1938, p. 424).

E. R. Squibb & Sons, New York.

Refined Tetanus Toxoid, Alum Precipitated-Squibb.—Marketed in packages of two 1 cc. vials (one immunization treatment). The preparation contains merthiolate 1:10,000.

CEVITAMIC ACID (See New and Nonofficial Remedies, 1938, p. 480).

Cevitamic Acid-Abbott.—A brand of cevitamic acid—N. N. R.

Manufactured by the Abbott Laboratories, North Chicago. No U. S. patent or trademark.

Tablets Cevitamic Acid-Abbott, 0.025 Gm.

Tablets Cevitamic Acid-Abbott, 0.1 Gm.

EPHEDRINE ANHYDROUS (See New and Nonofficial Remedies, 1938, p. 225).

Ephedrine Alkaloid Anhydrous-Gane and Ingram.—A brand of ephedrine anhydrous—N. N. R.

Manufactured by Gane's Chemical Works, Inc., New York (Gane & Ingram, Inc., New York, distributor). No U. S. patent or trademark.

EPHEDRINE HEMIHYDRATE (See New and Nonofficial Remedies, 1938, p. 226).

Ephedrine Alkaloid Hemihydrate-Gane and Ingram.—A brand of ephedrine hemihydrate—N. N. R.

Manufactured by Gane's Chemical Works, Inc., New York (Gane & Ingram, Inc., New York, distributor). No U. S. patent or trademark.

SATURDAY, OCTOBER 1, 1938

THE FOOD, DRUG AND COSMETIC ACT BEGINS TO FUNCTION

The month of July witnessed the beginning of enforcement of the Federal Food, Drug and Cosmetic Act of 1938. While the majority of the provisions of the act will not become effective until next June, dangerous drugs and dangerous cosmetics are immediately subject to the new law. Moreover, the provisions concerning the introduction of new drugs are also in effect.

The American Medical Association took an active part in procuring the enactment of the Federal Food and Drugs Act of 1906, which in its final form was obviously inadequate to accomplish the purposes for which it was intended. The Association has cooperated and is cooperating to the extent of its ability in bringing about the enforcement of that act and of its several amendments, and through THE JOURNAL, the Bureau of Investigation and its Councils has endeavored to keep the public and the profession informed about many harmful, deleterious or unscientific preparations. The Association proposes to follow the same policy with respect to the new act.

Although the present act is not nearly perfect, it has removed certain restrictions; the government may now proceed to act against products not previously within the purview of the law. Many years ago the Bureau of Investigation published a report on irrational or other dangerous cosmetic preparations for dyeing eyebrows and eyelashes. One particularly (Lash Lure) was reported to contain the dangerous paraphenylenediamine mixture. THE JOURNAL called attention to cases of blindness which followed the use of this preparation by some persons. The Food, Drug and Cosmetic Administration of the United States Department of Agriculture in its report for the month of July states that it has proceeded against "Lash Lure" and other similar preparations. The manufacturer of "Lash Lure" has notified the administration through its attorney that it was ceasing shipments immediately.

Physicians not long ago were urged to the use of a product called Causalin. THE JOURNAL pointed out its

deficiencies and more recently a critical report¹ was issued by the Council on Pharmacy and Chemistry. In this report the Council indicated that Causalin was apparently a mixture containing an aminopyrine preparation and a derivative having chemical resemblance to cinchophen. Now the firm has been cited by the government because, the government alleges, the subsidiary label statement "Aminodimethyl-pyrazolon-Quinoline-sulphonate" was a false representation of the composition of the medicine, since other significant ingredients were present. The government alleges that the product, a pain-relieving preparation, is dangerous to health when used in dosages or with the frequency prescribed, recommended and suggested in the labeling.

Of much interest to physicians is the recent ruling of the Food and Drug Administration on sulfanilamide. Under the dangerous drugs provision of the new Food, Drug, and Cosmetic Act sulfanilamide is prohibited from being sold to the public in "patent medicines" so far as:

It is the consensus of qualified experts that sulfanilamide is a valuable aid in the treatment of several serious disease conditions when the dosage is properly adjusted to the requirement of the individual patient and frequency of dosage and duration of treatment are intelligently and expertly directed. It is further the consensus of such experts that, when used under other conditions, it is a dangerous drug, capable of causing serious injury and even death.

In the light of these facts, careful consideration has been given to the status of sulfanilamide under the provisions of the Food, Drug and Cosmetic Act which deals with traffic in dangerous drugs.

Sulfanilamide and drug preparations containing sulfanilamide or related compounds for indiscriminate use by the general public, in a manner which constitutes a serious danger to health, are, when found in interstate commerce, actionable, in the opinion of the Food and Drug Administration, under section 502 (j) of the Federal Food, Drug and Cosmetic Act, which section of the law is now in effect.

Similar ruling has been made for aminopyrine, for cinchophen and for neocinchophen.

Another item in the report of the Food and Drug Administration for the month of July refers to an investigation of a number of food products. Among them was a consignment of curry powder heavily contaminated with lead. Among the allegations made was that against 577 cans of a malted milk food drink containing little or no malted milk; 19,062 pounds of a so-called cocoa containing at least 12 per cent added vegetable gum; 426 packages of butter cookies containing little or no butter; 19 gallons of so-called lemon juice, found to be an imitation; 150 gallons of refined soy bean oil which was found to be 90 per cent mineral oil; a sizable quantity of horseradish made up entirely of parsnips flavored with mustard oil and vinegar, and 104 sacks of caraway seed from which nearly all the essential flavoring oil had been distilled.

The Food and Drug Administration continued its campaign of confiscation against unsterile gauze bandages and absorbent cotton, of which there seems to be

1. Causalin (Causyth) Not Acceptable for N. N. R., J. A. M. A. 109:506 (Aug. 14) 1937.

a profuse amount on the market. Among other confiscations were sixty bottles of milk of magnesia with cascara and sixty-three bottles of milk of magnesia with vanilla and sugar, both failing to conform to their label claims of composition.

The Federal Trade Commission also has serious responsibilities in the regulation of advertising to the public. Recently it issued a release in which it is indicated that the U. S. District Court of Chicago has issued an order temporarily restraining the Hartman chain of drug stores from disseminating in any manner false advertisements concerning a weight reducing compound. The bill of complaint alleges that the defendant has falsely advertised the product for the purpose of inducing, or as a product which is likely to induce, its purchase as a weight reducer. According to the complaint the advertisement is false. Not only is the product not widely prescribed by practicing physicians, but also the advertisement fails to reveal that the use of this product under the conditions recommended may be injurious to the health of the user by causing loss or serious impairment of eyesight. It was brought out that the active ingredient in the drug is known as dinitrocresol. This is essentially similar in action to dinitrophenol. An affidavit by Dr. Harry Gradle states that he treated a Chicago woman suffering from a cataract of each eye following the use of the nostrum. THE JOURNAL and the Council on Pharmacy and Chemistry have frequently warned against the use of the nitrophenol type of weight reducing preparations.

The medical profession will follow with interest the further work of the Food and Drug Administration and the Federal Trade Commission since they have been fortified with new laws to combat deception. Some time may elapse before the courts will pass judgment on the new laws; until this is done their exact status will not be known. The medical profession will always be found solidly with the government in its protection of the public against the exploiters of impure or harmful foods, drugs and cosmetics.

PROTRUDED INTERVERTEBRAL DISK, BACK PAIN AND SCIATICA

Medical periodicals of the past few years contain a number of contributions dealing with the rupture of the intervertebral disk and its herniation into the spinal canal as a cause of intractable back pain and sciatica. The center of interest for the student of these conditions seems to have shifted from spondylolisthesis to the rupture of the nucleus pulposus. The exact knowledge of the anatomy and embryology of this long neglected structure dates back to the anatomic studies of von Luschka (1858). A correct clinical or pathologic approach to the subject of the intervertebral disk, however, is a recent contribution, the result of the accurate and painstaking necropsy studies of the Dresden pathologist Schmorl.

Briefly the intervertebral disk consists of an outer dense fibrocartilage firmly attached to the adjacent vertebrae and forming a strong but elastic ring, annulus fibrosus or lamellosus, acting as an envelop for the interior semifluid mass of fibrogelatinous pulpy center, the nucleus pulposus. The firm fluid cushion or shock absorber is subject, as pointed out by Keyes and Compere,¹ to the laws of fluids. It is incompressible and confined to its normal shape and position by the strong and elastic annulus fibrosus. The amount of compression of the intervertebral disk will therefore depend on the elasticity and strength of the annulus fibrosus. The incompressibility of the nucleus pulposus lends to it the function of transmitting the static and muscular forces from one vertebra to the next and establishes it as the axis of motion on which each vertebral body must work.

Schmorl found in his necropsy studies of the spine that the intervertebral disk is often involved in pathologic changes, the most common being prolapse (38 per cent) of the nucleus pulposus into the spongiosa of the adjacent vertebra, leading later to the formation in the involved vertebra of the so-called Schmorl nodules. He discovered further that in about 15 per cent there were small posterior prolapses of the nucleus pulposus beneath the posterior longitudinal ligament but concluded that they rarely, if ever, produced clinical symptoms. He advanced the concept of the rupture of the nucleus pulposus as the starting point for a number of pathologic changes in the spine, the rupture being facilitated or caused by the degenerative changes in the annulus fibrosus, with mild trauma as a second factor.

The earliest clinical report of this condition was that of Goldthwaite, who reported a case of sciatica and paraplegia due to a posterior herniation of the intervertebral disk at the lumbosacral junction. He suggested that such displacements might be the cause of many cases of sciatica, lumbago and back strain. A similar case was reported by Middleton and Teacher of England, but both observations attracted little interest. In the next decade and a half, a number of neurosurgeons, among them Elsberg, Stookey, Bucy, Adson and Dandy, reported cases of enchondroma developing from the intervertebral disk and causing spinal cord compression. In 1934 Mixter and Barr² reported from the Massachusetts General Hospital a series of nineteen cases of rupture of the disk, establishing it as a clinical entity and a cause of intractable back pain and sciatica. In 1935 Mixter and Ayer³ added observations on fifteen more cases. In THE JOURNAL, Love and Walsh⁴ have reported 100 cases in which the protruded inter-

3. Mixter, W. J., and Ayer, J. B.: Herniation of Rupture of the Intervertebral Disk into the Spinal Canal, *New England J. Med.* **213**: 385 (Aug. 29) 1935.

4. Love, J. G., and Walsh, M. N.: Protruded Intervertebral Disks, *J. A. M. A.* **111**: 396 (July 30) 1938.

vertebral disk was removed at operation. It appeared that the enchondromas of the earlier reports were in reality prolapsed nuclear material impinging on the cord, cauda equina, nerve roots or posterior longitudinal ligament. The favorite location is the lower lumbar region, probably because it is subjected to the greatest mechanical stress in heavy lifting or pushing.

The clinical diagnosis of a protruding disk as the cause of sciatica is based, according to Love and Walsh, on a history of trauma to the back with persistent or recurrent low back and sciatic pain, with diminished or absent achilles reflex, and an increased total protein content of the cerebrospinal fluid. The diagnosis is confirmed and the protruded disk identified by fluoroscopic examination of the spinal canal after the subarachnoid injection of iodized oil through a lumbar puncture needle. If on examination of the movements of the opaque oil in the spinal canal a persistent defect characteristic of protruded disk is observed, and if a lesion located at that level could account for the patient's pain, surgical removal of the protruded portion of the disk is indicated. Barr⁵ has reported that fifty-four patients of fifty-eight operated on were either well or markedly improved, and Love and Walsh state that there has not been a single recurrence in their series of 100 cases. The incidence of this entity is unknown. According to Barr, 90 or 95 per cent of the patients who have sciatica recover either spontaneously or after conservative treatment and do not need to be subjected to the highly technical and possibly dangerous examination with iodized oil. It is well, perhaps, to heed his admonition that there is some danger that too many patients will be subjected to examination with iodized oil or to radical exploratory surgery as a result of the untempered enthusiasm of certain men who assume that this entity is the cause of all sciatica.

Current Comment

ASCITIC FLUID TRANSFUSION

Davis and White¹ of the Department of Surgery, George Washington University School of Medicine, have reported recently that human ascitic fluid may be successfully substituted for whole blood in transfusion. Ascitic fluid has the advantage of low cost, as a constant source of supply is present in every hospital. The fluid is readily maintained in a sterile condition and does not deteriorate on storage. While their conclusions are based solely on experiments with transfusion in dogs, they see no reason why their results should not be equally applicable to man. Various substitutes for whole blood have been suggested and tried in transfusion. Gum-saline and gelatin-saline solutions were extensively used during the World War. More recent tests have been with hemoglobin Ringer's solution, or with whole blood or plasma obtained from the placenta, umbilical

cord or cadaver. In their attempt to find a less objectionable substitute, the Washington surgeons withdrew peritoneal exudate from patients suffering from cardiac decompensation or portal cirrhosis. The fluids were filtered through gauze and stored without preservative at 5 C. for varying periods up to five months. Bacteriologic examinations made at intervals by the blood-agar plate method showed that the fluids were sterile. Compatibility tests with the blood of the prospective canine recipients were made before transfusion. The dogs weighed from 7 to 10 Kg. and were given pentobarbital sodium anesthesia. Shock was induced in these dogs by the gradual withdrawal of about 350 cc. of arterial blood. The average initial blood pressure (kymograph tracing), about 150 mm. of mercury, was reduced to about 55 mm. by this bleeding. About 500 cc. of ascitic fluid was warmed to 33 C. and allowed to flow into the femoral vein at the rate of 15 cc. per minute. As a result of this ascitic transfusion the carotid pressure was raised to 120. The animals survived indefinitely and did not show immediate or delayed transfusion toxicity. Albuminuria, glycosuria or hematuria was never observed. Whether or not retransfusion after an incubation period of from three to five weeks would produce retransfusion shock was not tested. The possibility of evaporating the ascitic fluid to dryness and redissolving before transfusion has not yet been tried.

EFFECT OF INSULIN IN VITRO

One of the most important of the unsolved problems in the biologic sciences is the mechanism of the action of insulin. The injection of insulin promotes the oxidation of carbohydrate but the exact mode of action of the hormone in stimulating these processes is not certain. The many physiologic variables present in the organism have made it extremely difficult to separate the processes involved in the action of insulin, even though the effects of the hormone have been rather completely postulated from work on the intact diabetic organism. Many efforts have been made to simulate the results of the activity of insulin by a large variety of in vitro experiments. The complete description of the mode of insulin action would no doubt greatly increase the amount of available information regarding carbohydrate metabolism and might perhaps also indicate how intimately the oxidation of fatty acids is related to the simultaneous combustion of carbohydrate. Past work has, however, yielded for the most part essentially negative results. The importance of the problem increases the significance of a recent article¹ describing an effect of insulin on oxidations in isolated muscle tissue. In a study of the respiration of minced pigeon breast muscle, in the Warburg apparatus, it has been demonstrated that the addition of insulin retards the decline in respiration, which under these conditions ordinarily begins from half an hour to an hour after the initiation of the experiments. The falling off in the respiration is also inhibited by the addition of citrate or certain compounds derived from citrate (succinate, fumarate) all of which have been postulated as inter-

mediates in the biologic oxidation of carbohydrates.² Particularly noteworthy is the fact that insulin has its greatest effect if added together with citrate and muscle extract, and it is therefore concluded that insulin acts as a catalyst in a "citric acid cycle".² The exact significance of these results cannot be determined until many more experimental data have become available. The observations are perhaps most noteworthy because of the finding of a positive effect for insulin. It should be pointed out, however, that the quantities of insulin required to demonstrate this in vitro action are approximately twenty times greater than the amounts required to produce an effect in the intact organism. Quite likely the entire mechanism of the action of insulin is not attributable to a single primary stimulation of the oxidation of carbohydrate. Nevertheless the results suggest the possibility of demonstrating in vitro other primary effects of insulin on carbohydrate metabolism.

Association News

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES HELD IN CHICAGO, SEPT. 15-17, 1938

Meetings of the Board of Trustees were held on Thursday, Friday and Saturday of the week of the special session of the House of Delegates, and the following actions were taken:

ST. LOUIS SESSION

May 15-19, 1939, was the date set for the St. Louis session of the Association, and the nomination by the St. Louis Medical Society of Dr. Robert E. Schlueter as chairman of the Local Committee on Arrangements was confirmed.

APPOINTMENTS

Drs. George Blumer and Paul J. Hanzlik were reappointed on the Committee on Scientific Exhibit for a period of three years.

Drs. William P. Wherry, Paul Titus, John R. Neal, Charles B. Pinkham, S. S. Goldwater, Malcolm T. MacEachern, Donald Balfour and Alan M. Chesney and Rev. Alphonse M. Schwitalla were elected to constitute an Advisory Committee to the Council on Medical Education and Hospitals.

APPROPRIATIONS

Appropriations were made for special exhibits on anesthesia and fractures for the St. Louis session of the Association; for an investigation by the Council on Foods of the lead content of certain foods, particularly products used in infant feeding, and for the expansion of the public relations activities of the Association.

PUBLICATION OF BOOKS

Authorization was given for the printing of a limited edition of the manual for periodic health examinations to meet current needs, and for the development of a new manual. Permission also was granted for the reprinting in book form, in English and in Spanish, of the series of articles on vitamins which appeared in THE JOURNAL.

POSTPONEMENT OF CONFERENCE ON MEDICAL PATENTS

Because of preparations for conferences and meetings that were not previously contemplated, it has been difficult to carry out the plan of calling a conference on medical patents early in the fall. This matter will be given further consideration at the November meeting of the Board.

MISCELLANEOUS

Numerous other matters received consideration, and many of these will be acted on at a later date.

2. Krebs, H. A.; Salvin, Ernest, and Johnson, W. A.: Biochem. J. 32: 113 (Jan.) 1938.

FORMER DELIBERATIONS

Appointments: The following appointments were made at the former meeting of the Board, and acceptances have been received:

Dr. Russell Haden to succeed Dr. L. R. Thompson as the Association's representative on the Division of Medical Sciences of the National Research Council for a period of three years.

Dr. Irvine McQuarrie to succeed Dr. Grover T. Powers on the Council on Foods.

Dr. Edmund V. Cowdry to succeed Dr. George W. Churchillman on the Commission on Standardization of Biological Stains.

Drs. L. D. Bristol, A. J. Lanza and C. D. Selby as additional members of the Council on Industrial Health.

Dr. W. W. Bauer to serve on Joint Committee on Nursing Service.

Dr. Morris Fishbein to represent the Association on the Joint Committee to Investigate the Problems of Indexing and Abstracting Services in the Major Fields of Research proposed by the American Library Association.

Drs. Allen H. Bunce, Thomas S. Cullen and Roger I. Lee to constitute the Committee on Scientific Exhibit.

RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company entitled "Your Health" will begin Wednesday, October 19, and run consecutively for thirty-six weeks. The program will be broadcast over the Blue network of the National Broadcasting Company each Wednesday at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).

These programs will be broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The program to be broadcast in the first group, together with their dates and their topics, are as follows:

October 19. What Is Health?
October 26. Growing Strong.
November 2. Seeing and Hearing Well.
November 9. Healthier Boys and Girls.

The following is a list of the stations connected with the Blue network of the National Broadcasting Company, but no assurance can be given as to how many of these stations will broadcast the program "Your Health":

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Regional Meetings.—The fall meeting of the Northeastern Division of the Alabama State Medical Association was held September 22 in Anniston. Among the speakers were Drs. James N. Baker, Montgomery, state health officer, on "Future Plans and Needs of the State Department of Health"; Seale Harris, Birmingham, "Gastrointestinal Symptoms and Management of Pellagra"; John W. Boggess Jr., Guntersville, "Some Clinical Observations in Asthmatic Cases"; Charles N. Carraway, Birmingham, "Intravenous Sodium Pentothal and Oxygen Anesthesia"; Bishop B. Warwick, Talladega, "Nasal Headaches"; and Jerre Watson, Anniston, "Some Errors in Diagnosis."—At a meeting of the Southeastern Division in Dothan August 11 the speakers were Drs. Gordon R. Smith, Ozark, on "Treatment of Chronic Ulcers"; Hugh Dent Johnson, Montgomery, "Modern Management of Acute Intestinal Obstructions"; Clarence R. Bennett, Eufaula, "Coma and Its Differential Diagnosis"; Archie E. Thomas, Montgomery, "Treatment of Syphilis in Pregnancy," and John L. McGehee, Memphis, Tenn., "Use of Living Fascial Transplants in Repair of Certain Types of Hernia."

ARIZONA

Harlow Brooks Navajo Clinical Conference.—The third Harlow Brooks Navajo Memorial Clinical Conference was held at the Sage Memorial Hospital, Ganado, August 29-31. Louis H. Evans, D.D., Pittsburgh, president, Board of National Missions, Presbyterian Church, gave the welcoming address. In addition to clinics, the following papers were presented:

- Dr. Philip Lee Travers, Gallup, N. M., The Development of the Work of Sage Memorial Hospital and the Harlow Brooks Memorial Navajo Clinical Conference.
- Dr. Bowman C. Crowell, Chicago, Bone Sarcoma.
- Dr. Carl F. Rusche, Los Angeles, Urinary Extravasation.
- Dr. John H. Patterson, Phoenix, Local Anesthesia in Major Surgery.
- Dr. Grover C. Penberthy, Detroit, Management of Certain Lesions of the Esophagus.
- Dr. William H. Daniel, Los Angeles, Proctology for the General Practitioner.
- Dr. Fred H. Albee, New York, Reconstruction Surgery of the Skeleton.
- Dr. Charles H. Arnold, Lincoln, Neb., Surgical Treatment of Nephroptosis.
- Dr. Joseph Madison Greer, Phoenix, Observations on Another Method of Pinning Fractures of the Neck of the Femur.
- Dr. E. Payne Pamer, Phoenix, A Plea for an Early Diagnosis and Radical Treatment of Gastric Carcinoma.
- Dr. Victor S. Randolph, Phoenix, Bronchography in Diagnosis of Pulmonary Disease.

ARKANSAS

District Meeting.—The Tenth Councilor District Medical Society held a meeting in Fort Smith September 20 with the following speakers, among others: Drs. Ira F. Jones, Fort Smith, on "Differential Diagnosis Between Gastric and Duodenal Ulcer from the Standpoint of the General Practitioner"; William R. Brooksher, Fort Smith, "Present Status of Irradiation Therapy in Breast Tumors" and Herman W. Hundling, Little Rock, "Diverticulitis of the Sigmoid." Clinics were held at Sparks Memorial and St. Edward's Mercy hospitals.

New Cancer Foundation.—The Elise A. Lake Foundation has been organized within the past year to cooperate with the free cancer clinic of the University of Arkansas School of Medicine, Little Rock. The foundation is sponsored by the Arkansas Federation of Women's Clubs and is named in honor of the late Mrs. Elise A. Lake, Hot Springs, a past president of the federation, who for a year or more before her death was active in a statewide educational campaign for the early diagnosis of cancer. Its object "shall be mutual counsel and helpfulness in uniting the influence and service of citizens of the state, in promoting education for early diagnosis and treatment of cancer and to raise funds for the Elise A. Lake Foundation to increase facilities for diagnosis and treatment of cancer" at the university cancer clinic. The foundation is now seeking funds to carry out its work and county units are being organized. At a dinner during the biennial convention of the federation of women's clubs in May, pledges and cash amounting to about \$1,200 were received. Mr. Lake, who was

named honorary chairman, had previously given the foundation its first pledge of \$1,000. Mrs. John F. Weinmann, Little Rock, is chairman. The late Dr. Harvey Thatcher, professor of pathology at the university medical school, was active in the organization of the foundation, and his successor, Dr. Albert F. De Groat, is now vice chairman. Physicians on the advisory council are Drs. Frank Vinsonhaler, dean of the medical school; Joy K. Donaldson, associate professor of surgery, and William B. Grayson, Little Rock, state health officer.

DELAWARE

State Medical Meeting.—The one hundred and forty-ninth annual meeting of the Delaware State Medical Society will be held in Dover at the New State House October 11-12, under the presidency of Dr. Clarence J. Prickett, Smyrna. Guest speakers will be:

- Dr. Isidor S. Ravdin, Philadelphia, Surgical Problems of Hypertension.
- Dr. Maurice C. Pincoffs, Baltimore, Arterial Hypertension.
- Dr. Edward A. Schumann, Philadelphia, The Classic Cesarean Section.
- Dr. Lawson Wilkins, Baltimore, Hypothyroidism in Children.
- Dr. Francis G. Harrison, Philadelphia, Blood Stream Infections in Urologic Cases.
- Dr. Richard A. Kern, Philadelphia, Clinical Allergy.
- Dr. David A. Cooper, Philadelphia, Indications for Surgery in the Treatment of Pulmonary Tuberculosis.
- Dr. Thomas M. McMillan, Philadelphia, The Problem of Heart Disease as It Stands Today.
- Drs. Kenneth E. Appel and James A. Flaherty, Philadelphia, Modern Trends in Psychiatric Therapy.
- Dr. Raymond A. Vonderlehr, U. S. Public Health Service, Washington, D. C., Present Day Control of Venereal Diseases from a State and National Viewpoint.
- Dr. Bernard P. Widmann, Philadelphia, The Status of X-Ray and Radium in Treatment of Cancer.

Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will deliver a public address Wednesday evening October 12 on "The National Health Program and American Medicine."

ILLINOIS

New County Sanatorium.—A tuberculosis sanatorium for Lake County is to be built near Waukegan with a PWA grant of \$193,091 and a fund of \$233,000 to be raised through a bond issue and a tax levy, *Hospital Management* reports. The sanatorium will have a capacity of ninety-two beds. There will also be a nurses' home and a physicians' residence.

Chicago

Golf Tournament.—Dr. August F. Daro was the first winner of the new Chicago Medical Society Championship Trophy, which is to be awarded annually to the champion in the annual golf tournament. Dr. Daro tied with Dr. Homer K. Nicoll with a score of 78 at the tournament at the Olympia Fields Country Club August 31 and the tie was played off at the North Shore Country Club September 18, with Dr. Daro the winner. Dr. Grover E. Johnson won the VanDersee Trophy with a gross score of 79 and Dr. Harry E. Mock the Sisson Trophy for low net with a score of 32-63-95.

New Research Building for Abbott Laboratories.—The fiftieth anniversary of the founding of Abbott Laboratories, pharmaceutical manufacturers, in North Chicago, will be celebrated October 7 with the dedication of a new laboratory building. There will be a special program in the building in the afternoon following an inspection tour in the morning. The speakers will be:

- Karl T. Compton, Ph.D., president, Massachusetts Institute of Technology, Cambridge, Mass., The University and the Public Welfare.
- Dr. Herbert M. Evans, Berkeley, Calif., professor of anatomy, Morris Herstein professor of biology, and director of the Institute of Experimental Biology, University of California Medical School, The Task and Spirit of Research.
- Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., Research and Public Health.

In the evening a program will be presented at the Palmer House with the following speakers:

- Harison E. Howe, Sc.D., Washington, D. C., editor, *Industrial and Engineering Chemistry*, The Contributions of Organized Chemistry.
- George D. Beal, Ph.D., assistant director, Mellon Institute, Pittsburgh, The Scientific Development of Drug Standards.
- Dr. Morris Fishbein, Chicago, Editor, THE JOURNAL, The Contributions of Medicine to the Public Welfare.

The new building is three stories high with an attic and basement, providing facilities for the chemical, bacteriologic, botanic, medical and pharmaceutical research activities of this firm. In addition to laboratories it contains a micro-analytic laboratory, a library with accommodation for 20,000 volumes, hot and cold rooms for stability studies, dark rooms on each floor for the use of optical instruments, one dark room for use as a laboratory for light sensitive reactions, and an air conditioned auditorium seating 800 persons.

INDIANA

Courses in Obstetrics.—Plans are under way to offer two week courses in obstetrics regularly throughout the year for Indiana physicians under the auspices of the department of obstetrics of Indiana University School of Medicine, Indianapolis, cooperating with the Indiana State Medical Association. It is planned to offer to four physicians at each session an intensive study in obstetrics and pediatrics. While attending the courses, the physicians may reside at the Coleman Hospital at the Indiana University Medical Center. There will be no charge for maintenance or tuition during the two week period.

City Receives Cancer Clinic.—The city of Indianapolis was formally presented August 18 with the new cancer clinic at the city hospital known as Patrick Hall. Edwin L. Patrick, Indianapolis business man, made the presentation; Mayor Walter C. Boetcher accepted the clinic, in turn presenting it to Dr. George W. Kohlstaedt, president of the city board of health. The cancer clinic is the gift of the late Mrs. Kathryn Cones Patrick, who in leaving a \$100,000 benefaction fund stipulated that her husband was to select the recipient. The new department, which offers complete equipment for the treatment of cancer, will be maintained from the income of a fund of \$60,000; \$40,000 of the original sum was used for equipment.

LOUISIANA

Society News.—The Tri-Parish Medical Association was addressed in Tallulah August 9 by Drs. John G. Snelling, Monroe, on "Medical and Surgical Aspects of Thrombocytopenic Purpura"; Dr. Arthur A. Herold, Shreveport, "A Story of Diabetes Mellitus with Evaluation of Present Day Treatment," and James B. Vaughn, Monroe, "The Reasons for the Change in Medical Economics."—The Bi-Parish Medical Society was addressed at the East Louisiana State Hospital, Jackson, August 3, by Drs. Isidore Cohn and Eugene B. Vickery, New Orleans, on "Vascular Clinics" and "Diagnosis and Treatment of Renal Diseases, with Some of the Newer Drugs with Results" respectively.—At a meeting of the Tangipahoa Parish Medical Society at the Hammond City Hall recently the speakers were Drs. Edgar Burns on urinary infections and Conrad G. Collins, vaginitis; both are of New Orleans.

MARYLAND

Group Instruction in Antepartum Care.—The first unit for group instruction in antepartum care was recently organized in the Southeastern Health District under Dr. John A. Skladowsky, district health officer, and Miss Rae D. Serpick, supervisor of public health nurses. Each Wednesday since the first meeting about twenty-five mothers have met to receive instruction and to witness practical demonstrations of the essential points in antepartum hygiene and infant care. Later it is hoped to establish a similar plan of health education for prospective fathers.

MASSACHUSETTS

Fellowships for Psychoanalytic Training.—The Boston Psychoanalytic Institute announces three Sigmund Freud fellowships in psychoanalytic training to begin in September 1939. The fellowships are open to graduates of class A medical schools who have had at least one year of general hospital training and two years' training in psychiatry. Applications must be filed before Feb. 1, 1939. Further information may be obtained from Dr. Moses Ralph Kaufman, chairman of the educational committee, 82 Marlborough Street, Boston.

MICHIGAN

Graduate Obstetrical Training.—Dr. Sprague H. Gardiner, senior instructor in obstetrics, University of Michigan Medical School, Ann Arbor, has been appointed in charge of a course of graduate instruction in obstetrics and gynecology. He will serve under the direction of Dr. Norman F. Miller, professor and head of the department of obstetrics and gynecology at the university. The course provides for two weeks of intensive training and observation in obstetrics, gynecology and allied subjects at University Hospital. Two practicing physicians are appointed for each period. Appointees for the quarter beginning October 1 include Drs. William G. Winter Jr., Nelson H. Clark, Harry C. Irvin, Holland; Gabriel D. Bos, Marvin B. Meengs, Muskegon Heights; William R. Lyman and George Loupee, Dowagiac; Clayton H. Palmer, Cassopolis; Sabina Kessler-Frux, Bay City, and Oscar D. Stryker, Fremont.

Pneumonia Program.—The Michigan State Department of Health will begin a program this fall to place production of pneumonia serum on the same basis as other biologic products so that state produced serum may eventually be made available to all residents of Michigan. The pneumonia program in Michigan was made possible by a grant of \$50,000 from the Commonwealth Fund to cover experimentation with the production of antipneumococcus serum for three years. The last legislature matched this amount, but the governor reduced it to \$30,000 because of unanticipated needs of relief. Distribution will start this fall, the use of state serum being restricted to the treatment of persons for whom serum is otherwise not available. The only other restrictions are that the determination of type be made by a registered laboratory and that physicians give the department of health a report on cases in which state serum is used. Michigan now has seventy-four typing stations, all but two of which are located below the Bay City-Muskegon line, the other two being in Houghton and Marquette in the Upper Peninsula. Thus far eight serum distributing stations have been established, two in the Upper Peninsula and six in the Lower in Houghton, Marquette, Muskegon, Grand Haven, Grand Rapids, Lansing, Saginaw and Pontiac. Typing facilities are available in thirteen other counties in Lower Michigan and distributing centers will be established in these counties as rapidly as arrangements can be made with the medical societies in these counties. Present facilities will accommodate about one third of the people of the state outside of Wayne County. A subcommittee on pneumonia of the preventive medicine committee of the state medical society agreed to cooperate with the department by giving the program a prominent place on the state medical society's program and by providing speakers for the extension courses carried on throughout the winter jointly by the state medical society and the University of Michigan.

MINNESOTA

Alumni Meeting.—The Minnesota Medical Alumni Association will hold a meeting October 14, the day of the University of Minnesota homecoming football game, at the University Hospitals, Minneapolis, under the chairmanship of Dr. Harold G. Benjamin. Clinics will be conducted in Todd Amphitheater by Drs. Ralph T. Knight in anesthesia; Horace Newhart, otolaryngology; Irvine McQuarrie, pediatrics; Owen H. Wangenstein, surgery; John L. McKelvey, obstetrics; Cecil J. Watson, internal medicine, and John C. McKinley, neurology. In the evening a dinner at the Minnehaha Club will be held in honor of Dr. Jennings C. Litzenberg, retiring head of the department of obstetrics.

MISSISSIPPI

District Meeting.—Dr. George W. Crile, Cleveland, addressed the Northeast Mississippi Thirteen-County Medical Society, Amory, September 20 on "An Analysis of the Indications and End Results of Surgical Treatment in 425 Cases of Essential Hypertension." Dr. J. Rice Williams, Houston, discussed "X-Ray Therapeutics" and Dr. William A. Evans, Aberdeen, "Preventing Pneumonia."

MISSOURI

Lectures on Obstetrics and Pediatrics.—The Missouri State Medical Association is sponsoring a series of lectures throughout the state on obstetrics and pediatrics as a continuation of a program begun in July. The speakers are Drs. Oscar F. Bradford, Columbia, and Paul F. Fletcher, St. Louis, who address lay groups the first four days of a week, on the importance of visiting a physician early in pregnancy, continuing under the physician's care until the baby is born and at least 1 year old. On the afternoon or evening of Friday of each week a meeting of physicians of the counties, sponsored by the medical societies, will be addressed by Dr. Fletcher and Dr. Bradford.

NEW HAMPSHIRE

Blood Test Required for Marriage License.—New Hampshire's law requiring a blood test for syphilis of all persons seeking licenses to marry, enacted in August 1937, became effective October 1. Before a town or city clerk issues a license, he must have in his possession a physician's statement that neither applicant is afflicted with syphilis or if afflicted is not in a stage in which the disease may become communicable. This statement must be accompanied by a record of a standard blood test. The result of the laboratory test is confidential and does not become part of the marriage record. To be acceptable the test must be made at the state laboratory

of hygiene at Concord. No charge is made for the laboratory service. Out of state applicants must conform to the requirements laid on New Hampshire residents.

NEW JERSEY

State Society Checks Need for Medical Care.—In connection with its survey of the need and supply of medical service, the Medical Society of New Jersey in July invited every person in New Jersey in need of medical care and unable to obtain it to communicate with the society's office in Trenton. The announcement was made through newspapers and radio channels. The society reports that in the first ten weeks 120 requests were received and all were turned over to the medical societies in the counties in which they originated. The requests were promptly investigated and care provided when it was needed. It was found that many requests came from persons who had already had medical care but were dissatisfied for various reasons. Requests came principally from persons who had no funds and did not know how to go about obtaining medical care. The society's report points out that 120 persons who apparently believe themselves unable to obtain medical care is a small proportion out of a state population of more than four million, that care was actually provided for some who did not know how to obtain it, and that newspapers lauded the plan as an effort to make medical care available.

NEW YORK

Cornerstone Laid for New Academy Home.—The Rochester Academy of Medicine held an official ceremony of laying the cornerstone of its new home August 22. A residence, presented to the academy recently by the daughters of the late Edmund Lyon, is being remodeled and a \$60,000 auditorium is being added. Dr. Albert D. Kaiser, president of the academy in 1937, made the principal address and the present president, Dr. David B. Jewett, presided. Dr. William W. Percy has been named to a newly created position of executive director. His task will be to coordinate the functions of the academy and to supervise the moving into the new building. The former home of the academy has been sold to the University of Rochester.

New York City

Hospital News.—The New York Polyclinic Medical School and Hospital announces the opening of the urologic department in its new clinic building under the supervision of Drs. Joseph F. McCarthy, Daniel A. Sinclair, David Geiringer and Howard S. Jeck and their associates.

Unusual Prevalence of Whooping Cough.—More than 400 cases of whooping cough are being reported weekly to the New York City Department of Health, it was announced September 4. So far this year there have been 8,552 cases with seventy-two deaths. In the corresponding period of 1937 there were 2,646 cases and twenty-nine deaths, it was said.

Meetings of the Academy.—The New York Academy of Medicine announces a change in policy for its stated monthly meetings. To stimulate interest, programs for the coming year have been arranged to provide consideration of controversial issues. In certain instances, according to the *Bulletin*, discussion has been devised to invite conflicting opinions on measures now before the medical profession. The first meeting will be held October 6 and the subject will be "Evaluation of Sulfanilamide Therapy." Dr. Eli K. Marshall Jr., Baltimore, will speak on "Fundamental Problems of Chemistry and Pharmacology—Mechanism of the Action" and Dr. Reuben Ottenberg, "Clinical Aspects." The discussers will be Drs. Francis G. Blake, New Haven, Conn., on erysipelas; Emanuel Appelbaum, meningitis; Homer F. Swift, rheumatic fever; William E. Studdiford Jr., gonorrheal conditions and postpartum infection.

Attempt to Smuggle Narcotics in Ice Cream.—Three men were arrested as would-be smugglers of narcotics September 20 on evidence showing they had attempted to send 77 grains of heroin to two prisoners who were being questioned in the office of the United States marshal. The men ordered ice cream and sandwiches to be delivered from a restaurant to the two prisoners. When it was prepared the men asked to see the ice cream, and the man at the counter saw the customer put something in the package. When the men had gone the restaurant clerk telephoned the marshal's office, where investigation revealed the capsule of heroin. The three men were already under indictment for conspiracy to violate the narcotic law and were arrested in court after they had pleaded guilty to the first charge. One was sentenced September 23 to eight years in prison on the old indictment; sentence for the other two was deferred. The two men for whom the smuggled heroin was intended were also sentenced on the same old indictments to terms of three and eight years.

NORTH DAKOTA

Special Society Organized.—The North Dakota Society of Obstetrics and Gynecology was recently organized with the following officers: Drs. James F. Hanna, Fargo, president; John H. Moore, Grand Forks, vice president, and August C. Orr, Bismarck, secretary.

OHIO

Regional Annual Meeting.—The ninety-fourth annual meeting of the Northwestern Ohio Medical Association will be held in Defiance October 4 under the presidency of Dr. Edward B. Pedlow, Lima. Among the speakers will be:

- Dr. Harold N. Cole, Cleveland, Precancerous Dermatoses and Malignancy of the Skin.
- Dr. Robert L. Schaefer, Detroit, Clinical Indications for the Anterior Pituitary-like Hormone.
- Dr. William Halsey Barker, Baltimore, Sulfanilamide.
- Dr. Henry W. Meyerding, Rochester, Minn., Displacement of the Lumbosacral Spine Associated with Backache.
- Dr. Emil Novak, Baltimore, Endocrine Aspects of Sterility.

The meeting will be preceded by a golf tournament Monday afternoon October 3.

OKLAHOMA

Courses in Venereal Disease.—With funds appropriated under the LaFollette-Bulwinkle bill, a series of lectures for physicians on venereal disease will begin October 3 in four counties to run for five weeks. The lectures will be given Mondays at Claremore, Rogers County; Tuesdays at Pawhuska, Osage County; Wednesdays at Bartlesville, Washington County, and Thursdays at Vinita, Craig County. Dr. David V. Hudson, Tulsa, will be the lecturer.

OREGON

Gift to University Medical School.—A gift of funds has been made to the University of Oregon Medical School, Portland, by Mrs. Julius L. Meier and her family in memory of the late Gov. Julius L. Meier. The initial gift amounts to \$50,000, it is announced, and will be added to funds for construction of the new University State Tuberculosis Hospital to be built on the university grounds. The legislature appropriated \$110,000 and the PWA allotted \$90,000 for the hospital; the added \$50,000 will make possible construction of forty beds in addition to the thirty-nine originally planned, Dr. Richard B. Dillehunt, dean of the medical school, announced. It will also make possible better outpatient facilities, it was said.

PENNSYLVANIA

Expand State Tuberculosis Facilities.—A new surgical unit at the State Sanatorium for Tuberculosis, Hamburg, was dedicated July 7 by Dr. Edith MacBride-Dexter, state secretary of health. Cornerstones were laid August 18 by Dr. MacBride-Dexter for a main infirmary, a children's preventorium and a dormitory for women employees at Pennsylvania State Tuberculosis Sanatorium, South Mountain.

District Meeting.—Dr. Martin E. Rehffuss, Philadelphia, addressed a meeting of the Second Council District, Medical Society of the State of Pennsylvania, Norristown, September 15, on "Gastric Neuroses." Dr. Frederick J. Bishop, Scranton, president of the state society, spoke on "The Status Quo of Medicine" and other state officers discussed current problems. Testimonials were presented to the following physicians who have been in practice fifty years: Drs. John L. Bower, Birdsboro; William T. Sharpless, West Chester; U. Grant Gifford, Kennett Square, and Nathaniel C. Peters, Northampton.

Philadelphia

Refresher Course for Nurses.—The Philadelphia General Hospital will offer a special four weeks refresher course to graduates of its school of nursing beginning October 1. One week will be spent in each of the major services (medicine, obstetrics, surgery and pediatrics), with experience in various special departments. The course will be repeated in January, April and June 1939. Graduates of the hospital who wish to take the course may communicate directly with the Director of Nursing, Miss Loretta M. Johnson, at the hospital.

UTAH

State Medical Election.—Dr. George M. Fister, Ogden, was named president-elect of the Utah State Medical Association at its annual meeting in Ogden September 1-3 and Dr. Claude L. Shields, Salt Lake City, was installed as president. Vice presidents elected were Drs. George L. Rees, Smithfield; Harry S. Scott, Salt Lake City, and Bliss L.

Finlayson, Price. The next annual meeting will be in conjunction with the Rocky Mountain Medical Conference in Salt Lake City, September 5-7, 1939.

VIRGINIA

Changes in Health Departments.—Rockbridge County has recently been separated from the Alleghany-Botetourt-Rockbridge health district to form a unit with the city of Lexington, with Dr. Robert P. Cooke continuing as health officer. Dr. James H. Gordon, Covington, has been appointed health officer of the new district of Alleghany and Botetourt counties. Dr. William Y. Garrett, Raven, has succeeded Dr. James N. Dudley, Eastville, as health officer of Northampton County. Dr. Charles H. Bondurant, Wytheville, has been made health officer of Wythe County and Dr. Eugene Bowie Shepherd, Baltimore, assistant health officer of Pittsylvania County.

WISCONSIN

Lectures on Infectious Diseases.—A series of lectures on infectious diseases will be presented by the committee on postgraduate education of the Medical Society of Milwaukee County with the following speakers: Drs. Henry C. Sweany, Chicago, on "Pulmonary Tuberculosis," October 10; John A. Kolmer, Philadelphia, "Value of Serums and Vaccine in General Medicine," October 18, and Joseph Brennmann, Chicago, "Contagious Diseases of Childhood," November 1.

WYOMING

State Medical Election.—Dr. John H. Goodnough, Rock Springs, was named president-elect of the Wyoming State Medical Society at its annual meeting in Laramie August 7-9 and Dr. John D. Shingle, Cheyenne, was installed as president. Dr. Marshall C. Keith, Casper, is secretary. The 1939 meeting will be held in conjunction with the Rocky Mountain Medical Conference in Salt Lake City, September 5-7.

GENERAL

Rocky Mountain Tuberculosis Conference.—The fourth biennial meeting of the Rocky Mountain Tuberculosis Conference will be held October 7-8 in Salt Lake City at the Hotel Utah. Twelve Rocky Mountain states make up the conference, of which Dr. Harry J. Corper, Denver, is president. Among the speakers will be:

Drs. John Zarit and Allen D. Riemer, Denver, Colo., Syphilis of the Lung.
Dr. Edward E. H. Munro, Grand Junction, Colo., Silicosis.
Dr. Leslie P. Anderson, Elma, Wash., Development of Allergy in Relation to Tuberculous Lesions in Young Adults.
Dr. Charles J. Kaufman, Denver, Vocational Therapy in the Management of Pulmonary Tuberculosis.
Dr. Kendall Emerson, New York, The Philosophy of the National Tuberculosis Association on Rehabilitation and After-Care.
Dr. Walter I. Werner, Albuquerque, N. M., Tuberculous Tracheitis.
At a banquet Friday evening Dr. Corper will deliver his presidential address on "Neo-Hippocratic Tuberculosis" and Dr. James J. Waring, professor of medicine, University of Colorado School of Medicine, Denver, will be the guest speaker on "Prognosis in Tuberculosis."

National Safety Congress in Chicago.—The Silver Jubilee meeting of the National Safety Congress will be held in Chicago October 10-14 at the Stevens Hotel. Addresses of medical interest include the following:

W. C. James, safety engineer, Portland Cement Association, Chicago, What About the Health of Quarry Workers?
Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, Personal Hygiene and Its Relation to Syphilis Control in the Food Industry.
Dr. Albert E. Russell, U. S. Public Health Service, Washington, D. C., Industry's Part in Combating Venereal Diseases.
Dr. Harold A. Vonachen, Peoria, Ill., What Can Be Done About Fatigue?
Dr. Harry E. Mock, Chicago, A Surgeon's Experience with Industrial Injuries.
Dr. Edward C. Holmblad, Chicago, Problems in the First Aid Treatment of Fractures.
Dr. Carey P. McCord, Detroit, Handicaps in the Diagnosis of Occupational Diseases.
Dr. Milton H. Kronenberg, Chicago, The Necessity for Uniform Absenteeism Records in the Industrial Health Program.
Dr. John J. Wittmer, New York, Has the Public Utilities Industry Any Occupational Health Hazards?

At the silver jubilee banquet Wednesday evening October 12 the speaker will be George E. Vincent, Ph.D., former president of the Rockefeller Foundation, New York.

Examinations in Obstetrics and Gynecology.—The American Board of Obstetrics and Gynecology announces that examinations for Group B candidates will be held in various cities of the United States and Canada Nov. 5, 1938, and Feb. 4, 1939. Application for the written examination for February must be filed with the secretary of the board before December 4. The general oral, clinical and pathologic examinations

for all candidates (groups A and B) will be conducted by the entire board, meeting in St. Louis May 15-16, 1939, during the week of the annual session of the American Medical Association. Applications for the group A examinations must be filed with the secretary before April 1, 1939. For further information and application blanks address the secretary, Dr. Paul Titus, 1015 Highland Building, Pittsburgh.

Central Association of Obstetricians and Gynecologists.—The tenth annual meeting of the Central Association of Obstetricians and Gynecologists will be held at the Hotel Radisson, Minneapolis, October 6-8, under the presidency of Dr. Robert D. Mussey, Rochester, Minn. Dr. Jennings C. Litzenberg, who recently retired as professor of obstetrics and gynecology at the University of Minnesota Medical School, Minneapolis, will be the guest of honor and will deliver an address entitled "The Making of a Conservative." Among the speakers will be:

Drs. Percy B. Russell Jr., and Michael J. Roach, Memphis, Tenn., B. Welchii Infections in Pregnancy.
Drs. Robert Jerome Prentiss and Warren W. Tucker, Iowa City, Cystography in the Diagnosis of Placenta Praevia.
Drs. Ralph A. Reis and Melvin B. Sinykin, Chicago, Myomectomy During Pregnancy.
Dr. Philip F. Schneider, Evanston, Ill., Prophylactic Endocrine Therapy in Surgical Menopause.
Dr. John Milton Singleton, Kansas City, Mo., The Effect of Alkaline Vaginal Preparations on the Huhner Test and Sterility.

A symposium on "Some Aspects of the Vascular Changes in Pregnancy Toxemias" is to be presented by the following members of the faculty of the University of Minnesota Medical School: Drs. Litzenberg, Maurice B. Visscher, Elexious T. Bell and John L. McKelvey. A banquet will be held Friday evening at which winners of the annual prize awards will present their papers. They are Drs. Fred L. Adair and John A. Haugen, Chicago, on "A Study of Suspended Human Muscle Strips in Vitro" and Drs. Ward F. Seeley, Roger S. Siddall and Walter J. Balzer, Detroit, on "Collapse Therapy for Tuberculosis in Pregnancy." At the banquet Dr. Mussey will deliver his presidential address on "Pelvic Pain" and Dr. Everett D. Plass, Iowa City, will speak on "The Birth of an Influence."

Government Services

Examinations for Army Medical Corps

The War Department announces an examination December 5-9, both dates inclusive, for qualification of candidates for appointment as first lieutenants in the U. S. Army Medical Corps to fill vacancies during the fiscal year 1939. The examination is open to all male graduates of acceptable medical schools who have completed one year's internship in an approved hospital and who will not be over 32 years of age at the time it will be possible to tender a commission. Boards of medical officers will convene throughout the United States to conduct the examination, which will consist of a physical examination, a written examination in professional subjects and a determination of the candidates' adaptability for military service. Licentiates of the National Board of Medical Examiners may be exempted from the written professional examination. Full information and application blanks will be furnished on request to the Adjutant General, War Department, Washington, D. C. Applications must be filed by November 19.

Public Health Service to Investigate Pneumonia

Field research projects in cooperation with state and local health departments have been established by the U. S. Public Health Service in seven states for an intensive investigation of the treatment and spread of pneumonia. Studies will be made in New Jersey, Pennsylvania, Illinois, St. Louis, Denver, New Orleans and a selected north central area in California. Three aspects will be covered: incidence of pneumonia by type, effectiveness of different serums in reducing pneumonia mortality and effectiveness of certain chemical substances in treatment. Funds will come from the regular scientific appropriation of the public health service, funds appropriated for public health purposes under the Social Security Act and state and municipal health budgets. Actual direction of the projects will be in the hands of the state or local health officers; the federal health service will lend technical assistance, act as consultant and in cooperation with local authorities tabulate and synthesize the results for publication. Public health service officers in charge of the studies are Drs. Joseph W. Mountin, Adolph S. Rumreich and Claude D. Head Jr.

"The Doctor's View of War"

The medical profession plays an active part in war, and the question What should be its attitude toward war is discussed in a small book, "The Doctor's View of War," edited by Dr. Horace Joules and written by nine physicians with the collaboration of a score of others. In a foreword Prof. J. A. Ryle says that our profession may be claimed to be the only pacifist one in the world. Yet the physician has become a partner in modern war, for he pronounces men fit for service, inoculates them against infections, supervises their health and patches them up again for the ordeal of battle. Professor Ryle remarks that it is an arresting, if at present fantastic, thought that our profession, which is more international than any other, could, if well coordinated, of its own initiative put a stop to war or at least so hamper the most bellicose government as to give it pause. Internationalism, he thinks, will eventually pave the way to peace. The great war occurred after a period of remarkable advance in medical science and on the western front was free from the usual outbreaks of infectious diseases, although new diseases appeared and there was a large incidence of minor infections. In the East the old enemies dysentery, typhus and malaria were endemic. War neuroses do not differ essentially from those of peace but because the precipitating factors are more violent they are more striking. In the great war the neuroses were clinically in two groups, officially called neurasthenia and hysteria. Those in the former group would now be called anxiety neuroses. An example of the injustice of war was that it was the merest accident, sometimes depending on the whim of a superior officer, whether a man was labeled "shell shocked" and sent to the hospital or had to face a court martial and firing squad for cowardice.

Some persons extol war as "nature's pruning hook," but the only biologic advantage it has is hybridization, of which they do not appear to be aware. This has made possible new and more and more favorable combinations of characteristics, but there is no reason for thinking that modern warfare has any eugenic value comparable to its destructiveness. There are no signs of biologic significance attaching to the great war; both victors and vanquished have the same menace of a rapidly falling population. If there is a selective effect within a national group it is probably dysgenic. The most optimistic view is that modern war will wreck the structure of society without inflicting any permanent biologic damage.

A deplorable practice in recent wars is disregard of the Red Cross. Hospital ships were sunk in the great war, and an attack on a Canadian hospital at Doullens is well authenticated. In Abyssinia the Red Cross was systematically bombed, and in the hospital at Dessie an American nurse was wounded and patients and their attendants were killed. Disregard of the Red Cross and bombing of cities is seen in the wars in Spain and China. The authors suggest that we appear to be on the verge of another age of barbarism. The hope lies in the stubborn democratic spirit of certain countries, which refuses to be intimidated by the philosophers of war absolute.

What can the medical profession do to avert this great calamity? After advocating strengthening of the League mechanism for collective security, the authors suggest that the medical association of one of the great civilized and democratic countries should take the lead by summoning the medical societies of all other countries to a conference, which should issue a pronouncement declaring it to be the will of the profession that for the sake of humanity a system of collective security should be established.

A Nurse Is a "Workman"

Under the workmen's compensation act a person is entitled to compensation for an accident arising in or out of his employment, but this has sometimes given rise to the question What constitutes employment? Are professional footballers or film stars employed in the legal sense? A decision of considerable importance to hospitals has been given in the case of a nurse who, acting under the directions of a ward sister in a municipal hospital, was preparing a poultice which exploded in the can in which it was being heated and injured her. She applied in court for compensation, but the judge held that she was not acting under a contract of service but under a contract to perform a service as an independent expert. The case was taken to the court of appeal. An argument took place as to whether a distinction could be drawn, as in a previous case, between the skilled technical duties of a nurse and her administrative or ministerial duties (which constituted employment without any doubt). One judge thought that it could and that when she was doing her work as a nurse the hospital was not liable to pay damages for her negligence or to compensate her. But the two other judges disagreed, and so she won her case. One said that her contract of service could not be divided and that, although the hospital might choose the person whom she was called on to obey, she was always under obedience to the hospital. The other judge said that negligence cases could not be applied to the question at issue. So manifestly were nurses in the service of their hospital that for this very reason it was necessary in a negligence case to inquire whether the hospital was liable for their negligence. The nurse was the servant of the hospital for general purposes and was under a contract of service with it under the workmen's compensation acts. The case was therefore sent back to the lower court for the judge to assess the compensation payable. The hospital was given leave to appeal to the highest court, the House of Lords.

Sir David Wilkie

The Edinburgh medical school has sustained a great loss by the death, at the age of 56, of Sir David Wilkie, professor of surgery. Born in Kirriemuir, the "Thrums" of the novelist J. M. Barrie, who was an intimate friend, he was educated at the University of Edinburgh, from which he graduated in 1904. In 1909 he took the Ch.M. degree and received a gold medal for his thesis. He became a fellow of the Royal College of Surgeons of Edinburgh in 1907 and of the similar college of England in 1918 and was made an honorary fellow of the American College of Surgeons in 1926. He was not only a great surgeon and a great teacher but an active member of many scientific boards, such as the Medical Research Council and the Scientific Advisory Committee of the British Empire Cancer Campaign, and was president of the section of surgery at the Edinburgh meeting of the British Medical Association in 1927.

The conservative treatment of acute infections was perhaps the most important part of his impressive teaching. The operative zeal which naturally followed Lister's great discovery was followed today, he said, by a fundamental change, as surgeons thought more on biologic and less on mechanical lines. The delicate and complex series of local and general changes which were the reaction to local infection had as their main objects localization of the infection and mobilization of the body forces. Nothing should be done which interfered with this process. At the recent annual meeting of the British Medical Association he opened the discussion on septic hand. He held that the profession had not sufficiently recognized the value of Bier's treatment. If the infection could be localized for only a short while, time was gained for general defense. His method was to apply the thin elastic bandage very lightly to the upper arm and leave it on for not less than twenty-two of the twenty-four hours, preferably continuously, for three days. If the bandage was applied correctly there would be no dusiness of the limb, only slight swelling, and the pain would be relieved. Incision of a

boil on the supposition that it is a form of abscess he held to be wrong in theory and mischievous in practice. Complete immobilization by strapping was the best treatment, and this held also for carbuncle, though in cases of severe toxic involvement antitoxic serum should be given. Experiments on rabbits convinced him that there was no active surgical treatment for general peritonitis. It might be prevented by timely surgical intervention and complications might require surgical aid, but confidence must be placed in medical remedies, serums, fluid replacement for vomiting, heat and morphine. Empyema he treated by aspiration, saying that the appalling death rate in the American army following open drainage of streptococcic empyema was necessary to bring home this lesson.

Use of Refrigerated Blood for Armies

The war clouds hanging over European countries have given an impetus to the study of whether refrigerated, or conserved, blood can be used on a large scale at or near the front. The employment of such blood during the present civil war in Spain has shown that it is an important addition to the resources of the military surgeon. At the June 29 meeting of the Académie de chirurgie of Paris, the head of a large army hospital, Dr. Maisonnnet, and Professor Jeanneney of Bordeaux, who has been one of the most enthusiastic advocates in France of the use of refrigerated blood, read a paper on the organization of a service to supply such blood during war. Extensive studies have shown that blood which has been kept at a temperature of 4 C. retains all its therapeutic qualities for from ten to fifteen days. The red blood cells, although they do not decrease in number, show slight morphologic changes such as contraction, a dentated appearance and expulsion of a part of the hemoglobin, and at the end of twenty days hemolysis can be noted. The leukocytes appear to undergo destruction as the result of refrigeration. From the chemical point of view, the blood gradually loses its dextrose content, but the phosphorus and the protein content increase, probably as the result of lysis of the leukocytes. As to the physical properties of the blood, especially its density and electrical conductivity, these show changes from the twelfth day onward. The biologic properties of the blood remain practically the same, especially as to grouping. The respiratory capacity does not show any alteration until about the twentieth day. These observations show that refrigerated blood, at least during the first week, resembles so closely fresh blood as to make it safe to use the former as a substitute. The authors cited the use of refrigerated blood during the civil war in Spain. A transfusion center was organized at Barcelona in 1936, the donors being nonmobilized civilians, especially women. From each of the 4,500 donors about 400 cc. was taken every month or so. During the first year 1,220 liters of blood was thus made available to be sent to the front either by trucks or by special automobiles equipped with electrical refrigerators similar to those in domestic use. On the insurgent side twenty transfusion centers were organized. Over 9,000 persons from 16 to 50 years of age served as voluntary donors, some of them more than twelve times. Every brigade has its transfusion service, and the blood can be given at the front by using boxes constructed on the principle of a vacuum bottle so as to keep it at the same temperature as in a refrigerator. The government surgeons use a citrated blood, whereas in the insurgent armies the whole blood method as advocated by Yudin of Moscow (described in an editorial in *THE JOURNAL* August 20) is employed. The results, as published in recent bulletins from both armies, have been equally satisfactory.

Maisonnnet and Jeanneney are of the opinion that refrigerated blood will render valuable service in future wars. Their experi-

ence in its use in peace times is limited to citrated blood. A French military surgeon, Pilod, in 1936 offered a plan for the organization of a transfusion or hematologic service for each division consisting of a chief and three aids who are specialists in the examination of donors and recipients as well as in giving transfusions. It should be the duty of such teams to obtain blood from slightly wounded or convalescent soldiers and to keep on hand a relatively large amount of blood of different groups. First aid and casualty clearing stations would thus be provided with flasks containing 250 cc. of blood from universal donors, which can be given intravenously by any surgeon. It would rarely be necessary to obtain blood from the personnel of the hospital corps. In addition to this service at or near the front, a service would be organized in every region of the country which would have as its objective the collection of a reserve supply from civilian donors, including blood from all four groups. This blood could be sent to the front by means of airplanes or automobiles equipped with apparatus to keep the blood at a low temperature. Professor Jeanneney, so that automobiles with refrigeration facilities can be dispensed with, is studying the use of a specially constructed box to contain a large number of flasks of conserved blood which can be kept at a temperature near 4 C. and can therefore be transported by ordinary army trucks. The blood can then be warmed before being used for transfusion.

Program of Therapeutic Union Meeting

This year's meeting of the Therapeutic Union will be held on October 12 at the Paris Medical School. The president is Prof. Maurice Loeper, and reports on the following subjects will be read: oxygen therapy, protein therapy of diabetes, vitamin therapy of diseases of the digestive apparatus, chlorophyll and cutaneous diseases, and continuous intravenous injection as a therapeutic method. A series of papers will be read on the part of sulfur in therapeutics. Information regarding the meeting may be obtained by writing to Dr. G. Leven, 24 rue de Téhéran, Paris 8.

French Syphilology and Dermatology Congress

This year's Syphilology and Dermatology Congress will be held in Paris October 12-14. The president is Dr. Milian, and the program includes reports on balanoposthitis by Dr. Bory, Professor Farre and Dr. Golay; on histamine in dermatosyphilology by Drs. Weissenbach and Jausson and Dr. Kitchevatz of Yugoslavia, and on agranulocytosis in dermatovenereology by Dr. Touraine, Professor Watrin, and Professor Marin of Montreal.

Hospitals in the German Reich in 1936

A comprehensive statistical report for the year 1936 on hospitals of the German reich has just been published. The total number of hospitals was 4,792 as against 4,864 in the year 1935. Of the total number 2,106 were classed as public, 1,552 as communal and 1,134 as private. The smaller number as against the year 1935 was due to the discontinuation of most of the smaller units, namely those having twenty-five beds and less. On the other hand, the number of regularly available hospital beds in the entire country had somewhat increased; it was 620,751 as against 614,888 in 1935. Accordingly there were available an average of 92.2 regular sick beds per 10,000 of population as against ninety-two in 1935.

The number of beds available in various classes of institutions enumerated in 1936 are set forth in table 1.

The gross number of patients treated in the nation's hospitals was 3.7 per cent higher than in 1935. The distribution of patients according to sex is shown in table 2.

As a consequence of the increased number of admissions the number of sick days spent in hospital increased by about 2.8 per

cent, reaching 180,552,492. Accordingly, despite the further decline in the average per patient stay in hospital, which sank from 35.2 to 34.9 days, the utilization of beds was extraordinarily greater, reaching nearly 80 per cent of capacity.

According to season the highest average patient population fell in November; the next highest averages were in February and March. The fewest admissions took place in April.

TABLE 1.—Beds Available in 1936

| Classification | Number | Beds |
|---|--------|---------|
| General hospitals | 3,196 | 338,683 |
| Hospitals for tuberculous adults | 187 | 24,319 |
| Hospitals for tuberculous children | 31 | 4,841 |
| Nursling and children's hospitals | 154 | 14,601 |
| Orthopedic hospitals | 47 | 9,080 |
| Eye hospitals | 102 | 3,153 |
| Hospitals for treatment of venereal diseases and dermatoses | 36 | 2,833 |
| Hospitals for chronic invalids and incurable patients | 117 | 19,536 |
| Hospitals and sanatoriums for mental diseases | 260 | 154,032 |
| Institutions for the feeble-minded | 64 | 23,670 |
| Hospitals for nervous disorders | 52 | 2,977 |
| Hospitals for alcoholic and other addicts | 18 | 807 |
| Lying-in hospitals | 204 | 9,358 |
| Other specializing institutions | 225 | 9,513 |
| Hospital units in penal institutions | 99 | 3,348 |

The gross number of deaths in all German hospitals is shown in table 3.

Although the mortality during the years from 1932 to 1934 remained at the same level, 4.7 per hundred patients, the rate rose to 4.8 in 1935 and to 4.9 in 1936. The influenza epidemics may be presumed to have played a part in this increase. Other possible factors are the increase in serious accidents following the revival of industry and the increasing tendency in recent years to hospitalize seriously ill patients a short time prior to death. Attention was recently called to the latter trend by the municipal medical councilor of Berlin (*THE JOURNAL*, April 30, 1938, p. 1501). Of 100 deaths within the German reich during 1936, 31.9 occurred in hospitals as against only 26.7 in the year 1932.

Table 4 illustrates the distribution of various types of obstetric cases.

TABLE 2.—Distribution of Patients by Sex

| Year | Total | Male | Female |
|------|-----------|-----------|-----------|
| 1935 | 4,994,000 | 2,352,000 | 2,642,000 |
| 1936 | 5,177,000 | 2,449,000 | 2,728,000 |

TABLE 3.—Number of Deaths

| Year | Total Persons Dying in Hospital | Male | Female |
|------|---------------------------------|---------|---------|
| 1934 | 215,561 | 112,687 | 102,874 |
| 1935 | 241,883 | 125,874 | 116,009 |
| 1936 | 254,127 | 133,735 | 120,392 |

The number of completed confinements in all hospitals increased by about 6.8 per cent as against the year 1935. On the other hand, the number of artificial interruptions of pregnancy performed in hospitals declined by about 28 per cent, apparently as a result of stricter control of the necessitating circumstances.

Particularly important to the national eugenic health policy is the determination of the proportion of institutional births to the total number. In 1936 1,312,053 babies were born in Germany; the per mille proportion of babies born in hospitals was 269.9 as against 251.2 in 1935. The number of institutional births has accordingly undergone not only an absolute increase

but an increase in proportion to the total number of births. The birth rates of certain localities have declined considerably as a result of increased hospitalization in confinement cases.

In the report under discussion, data on the hospitals of Austria are submitted for the first time since the country was annexed. In the year 1936, 287 hospitals were enumerated, fifteen of them institutions for the insane. There were ninety-six public hospitals with a total of 36,505 beds; 12,366 beds, namely one third of the total, were in hospitals for the insane. There were 191 nonpublic hospitals with a total of 15,682 beds; included in this group were five small hospitals for the insane with 553 beds and forty-seven sanatoriums with 2,679 beds. The total number of beds available in Austrian hospitals was accordingly 52,187 (77.8 per 10,000 of population); the bed capacity was thus smaller by some 14.4 per 10,000 than that of the German reich.

The supply of hospital beds differed widely in the various provinces of the Austrian federation. In Vienna, for example, there were 95.6 beds per 10,000 of population; for Burgenland, on the contrary, the corresponding figure was only 14.4.

The total number of persons hospitalized in Austria in 1936 was 583,171, of whom 21,080 were treated in hospitals for the insane. The total number of days in hospital was 16,051,928, of which 5,026,434 represented days spent in hospitals for the insane. The average stay in hospital was 27.6 days. The beds utilized represented 84 per cent of capacity, a somewhat larger proportion than in the German reich. During the year 23,937

TABLE 4.—Distribution of Obstetric Cases

| Confinements | Total Number | In Lying-in Hospitals and Services | Percentage |
|-------------------|--------------|------------------------------------|------------|
| 1935 | 321,310 | 248,638 | 77.4 |
| 1936 | 349,092 | 264,809 | 75.9 |
| Induced Abortions | | | |
| 1935 | 4,151 | 1,905 | 45.9 |
| 1936 | 2,982 | 1,301 | 43.6 |
| Miscarriages | | | |
| 1935 | 87,182 | 33,422 | 38.3 |
| 1936 | 88,667 | 35,817 | 40.4 |

persons died in hospitals, namely 4.1 per cent of the patient population and 26.9 per cent of all persons dying in Austria in 1936.

Dosage of Ultraviolet Radiation

Dr. Wucherpfennig's fundamental discussion of the dosage of ultraviolet radiation before the medical society of Münster, Westphalia, was based in part on his own investigation. Even if the practitioner has at his disposal a dosimeter for ultraviolet rays he is still in no position to evaluate accurately the biologic reaction of predilection in the individual case. It is assumed that the dosimeter will register precisely the most important biologic reaction, namely the erythema. The erythema, however, as has been demonstrated by the author and others, is peculiarly dependent on the sex and age of the patient and the nature of the disorder. Then too, erythema varies in character according to the region of the body irradiated. Difficulties which cannot be excluded from administration of even the most optimal physical dose may, however, be abolished if the operator gauges his therapeutic procedure by the erythema itself or, as Wucherpfennig calls it, the "erythematous threshold." For practical purposes one may consider this erythematous threshold of the ultraviolet current to be the weakest degree of reddening which is sharply defined against the adjacent unirradiated region within twenty-four hours after irradiation. The roentgen therapy then consists of some ten additional doses of radiation, administered at intervals of one week. Each dose must be about 30 per cent more powerful than the preceding one. This holds true for all ultraviolet current apparatus. The apparatus, for example the mercury quartz lamp and almost all carbon arc lamps with metallic salt carbons, usually emits

a short wave, erythema-producing, ultraviolet ray (an ultraviolet concentration of from 2,800 to 2,400 angstroms). Recent studies of the intermediary metabolism have demonstrated impressively the importance of the mentioned variations up to the average ultraviolet reaction. The investigations, although seemingly of only theoretical worth, have throughout a practical value as well. Cutaneous reactions to the ultraviolet rays produce, according to the degree of their intensity, metabolic processes which may be wholly disparate in character.

BELGIUM

(From Our Regular Correspondent)

Aug. 20, 1938.

The Order of Physicians Established by Law

The Chamber of Representatives has passed legislation establishing an Order of Physicians. This marks a red letter day in the history of the Belgian medical profession. Although for this body the new enactment represents the fruit of tentative negotiations which have been in progress for over a century, it may be said that the question has entered a phase of imminent realization only since 1924. In that year the Académie royale de médecine formally advocated the establishment of an official order of physicians. In recent years we have noted the successive steps in the evolution of this great reform, the social importance of which is well recognized. It seems appropriate to quote the memorable words of the minister Jaspar with regard to this problem: "When an important group such as the medical profession concerns itself with problems of deontology, morale, dignity and honor, it is a matter of interest not only to physicians. The new order of physicians, besides serving as a vital factor in the perpetuation of an organized medical profession, will serve as a strong bulwark to society as a whole." The new statute constitutes a veritable magna carta of Belgian medicine. Its more important provisions are as follows:

The Order of Physicians comprises all doctors of medicine, surgery and obstetrics resident and authorized to practice in Belgium whose names appear in the order's official register. Transitional regulations provide that all doctors of medicine, surgery and obstetrics resident in Belgium who wish to practice in this country must first have themselves enrolled on the order's official register. A provincial council of the order, having local jurisdiction over a particular practitioner, cannot refuse to enroll him unless he has been convicted of some act serious enough to warrant permanent exclusion from the practice of medicine in Belgium.

A physician barred from practice can demand and receive a personal hearing before the council of the order. He may be represented by one or several advocates. The council of the order will explain the motivation of its judgments as rendered.

There is created in each province a council of the order, having jurisdiction over all physicians resident in the province. The councils of the order are charged with upholding the standards of medical deontology, honor, propriety and dignity in their respective memberships. The councils also take cognizance, as competent authorities, of any instances of malpractice allegedly committed within the respective jurisdictions. The councils are empowered to regulate the scale and amount of professional fees in certain cases, namely (1) if serious lack of professional ethics is imputed, (2) on the joint request of two interested parties and (3) in compliance with a judicial request for expert opinion. No physician can be made liable to punishment on religious, philosophical, political, linguistic or syndical grounds or because of his affiliation with an organization concerned with practice of medicine among a particular group or class of persons. Any interference in the foregoing domains is forbidden.

Each council of the order is composed of active members and alternate members elected by the physicians whose names appear in the official list. The number of active and alternate members to be elected is fixed by the royal decree embodied in article 23. Each of the juridical arrondissements of a province shall have at least three representatives on the council. Election of members is by secret ballot. The right of voting is limited to two thirds of the seats provided for each arrondissement. The members of the council of the order, both active and alternate, are elected from among practitioners of Belgian nationality not under 35 years of age who are residents of the particular province and whose names have appeared for at least five years on the official lists of the order. The term of office is four years; members cannot be reelected to succeed themselves. Any member of a duly organized council of the order who absents himself without legitimate excuse from attendance at two consecutive meetings may be punished by admonition or by censure. The officers of a council of the order are elected from its membership; they are the president, vice president and secretary. Each council of the order is assisted in an advisory capacity by a magistrate of first instance appointed by the king. The king also appoints an alternate magistrate under the same conditions.

The superior council of the order of physicians is elected by members of the provincial councils of the order. To complete the membership of the superior council the king appoints one active and one alternate delegate from the faculties of medicine of the universities of Brussels, Ghent, Liège and Louvain. The four universities may submit to the king a list of at least three names. The superior council of the order has its seat at Brussels. It is the duty of the superior council to provide reasoned opinions on questions of general interest; among other things it collects the decisions of various councils with a view to establishment of a body of deontologic jurisprudence. The superior council is to initiate any measures necessary for the accomplishment of its objectives. If the legality of a final decision of the superior council is questioned it may be appealed to the court of cassation. If the latter tribunal finds that a decision has violated the spirit or letter of the statute the decision is set aside. The procedure of appeal to the court of cassation, with regard to both the wording and the time allowed, follows the usual conduct of civil cases. The attorney general may petition the court of cassation for review of a decision of questionable legality. Appeal to the high court is suspensive.

Marriages

WILLIAM HAPPER, London, England, to DR. GLADYS MORGAN of Guntur, Madras Presidency, India, August 15.

WALTER H. SIMMONS JR., Pine Bluff, Ark., to Miss Ruth Wackerman in Norfolk, Va., June 18.

ROBERT LATEINER, New Rochelle, N. Y., to Miss Dorothy Kasenetz of Mount Vernon, July 6.

FRANCIS N. NIMZ, Milwaukee, to Miss Marion Phillips of Stevens Point, Wis., June 28.

WALTER S. POLACHEK, Milwaukee, to Miss Shirley Witkowsky of Chicago, June 1.

OLIVER L. PUTTLER, Milwaukee, to Miss Bergliot Hefte of Staples, Minn., June 25.

JAMES H. GRESSETTE, St. Matthews, S. C., to Miss Mary Sims recently.

CLIFFORD R. SCHNEIDER, Milwaukee, to Miss Eunice Druse, June 25.

GEORGE LIBERMAN to Miss Pearl Cooper, both of Brooklyn, June 11.

DWIGHT MARTIN to Miss Evelyn Kienitz, both of St. Paul, recently.

BERNARD R. BONNOT, Canton, Ohio, to Miss Betty Mang, June 9.

Deaths

Clifford Clarence Robinson * East Chicago, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; fellow of the American College of Surgeons; at one time member of the board of managers of the Lake County Tuberculosis Sanatorium, Crown Point; surgeon to St. Catherine's Hospital, East Chicago, St. Mary's Hospital and Mercy Hospital, Gary, and St. Margaret's Hospital, Hammond; aged 57; died, July 12, in the Augustana Hospital, Chicago, of cerebral hemorrhage and pyelitis.

Melvin M. Franklin, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the Medical Society of the State of Pennsylvania; fellow of the American College of Surgeons; served during the World War; on the staffs of St. Joseph's Hospital, St. Mary's Hospital, Mercy Hospital and the Jewish Hospital and the Veterans Administration; aged 63; died, July 31, at Point Pleasant, N. J., of coronary occlusion.

William Henry Tefft * Colonel, U. S. Army, retired, San Antonio, Texas; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; entered the army as an assistant surgeon in 1903; was awarded the Distinguished Service Medal for services during the World War; rose through the various grades to that of colonel; retired March 31, 1937; aged 65; died, July 1, at Fort Sam Houston, of carcinoma of the pancreas.

Edwin A. Hamilton * Columbus, Ohio; Medical College of Ohio, Cincinnati, 1891; assistant professor of surgery, Ohio State University College of Medicine; fellow of the American College of Surgeons; past president of the Columbus Academy of Medicine; served during the World War; on the staffs of the White Cross Hospital and the University Hospital; aged 72; died, July 31, of arteriosclerosis and cerebral hemorrhage.

Samuel Walthall Budd * Richmond, Va.; Johns Hopkins University School of Medicine, Baltimore, 1909; formerly associate professor of pathology and embryology at the Medical College of Virginia; member of the American Society of Clinical Pathologists; on the staffs of the Retreat for the Sick, and St. Luke's Hospital, Richmond, and the Petersburg (Va.) Hospital; aged 55; died, July 27, of heart disease.

Charles Emeric Kerr Vidal, Troy, Mont.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1890, and University of Bishop College Faculty of Medicine, Montreal, Que., 1890; member and past president of the Medical Association of Montana; served during the World War; at one time superintendent of the Montana State Tuberculosis Sanitarium, Galen; aged 68; died, June 20.

Rudolph Rix, Omaha; John A. Creighton Medical College, Omaha, 1899; member of the Nebraska State Medical Association; formerly professor of gynecology and clinical gynecology at his alma mater; past president of the Omaha-Douglas County Medical Society; on the staffs of the Evangelical Covenant Hospital and the Douglas County Hospital; aged 67; died, July 14, of coronary thrombosis.

Edward Ryan, Kingston, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1889; formerly professor of psychiatry and associate professor of surgery at his alma mater; at one time mayor; served during the World War; in 1927 was appointed director of hospital services for the province of Ontario; formerly superintendent of the Ontario Hospital; died, July 23.

Charles Rex Kennedy * Omaha; University of Nebraska College of Medicine, Omaha, 1905; professor of clinical surgery at his alma mater; fellow of the American College of Surgeons; surgeon to the Nebraska Methodist Episcopal Hospital; division surgeon to the Union Pacific Railroad; aged 56; died, July 29, in Nevis, Minn., of pulmonary edema.

Francis J. Brennan, Oshkosh, Wis.; Marquette University School of Medicine, Milwaukee, 1931; member of the State Medical Society of Wisconsin and the Radiological Society of North America; aged 34; on the staff of the Mercy Hospital, where he died, July 7, of duodenal ulcer, hemorrhage and acute bilateral nephritis.

John A. K. Birchett Sr. * Vicksburg, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1891; past president and secretary of the Warren County Medical Society; on the staff of the Vicksburg Infirmary; aged 71; died, July 22, of coronary thrombosis and arteriosclerotic heart disease.

Robert R. Curtis, Temple, Texas; University of Louisville (Ky.) Medical Department, 1894; member of the State Medical Association of Texas; formerly city health officer; on the staff of the Scott and White Hospital; aged 67; died, July 20, in a local hospital, of malignancy and mesenteric thrombosis.

Russell Edwin Olson, Milwaukee; Marquette University School of Medicine, Milwaukee, 1916; member of the State Medical Society of Wisconsin; served during the World War; on the staffs of the Misericordia and St. Joseph's hospitals; aged 44; died, July 14, of portal cirrhosis.

Howard Orville Lienhardt * North Kansas City, Mo.; St. Louis University School of Medicine, 1912; served during the World War; formerly member of the school board; aged 50; on the staff of the Research Hospital, Kansas City, where he died, July 3, of bronchogenic carcinoma.

Wylls Royce Hodges, Cumberland, Md.; Southern Homeopathic Medical College, Baltimore, 1900; member of the Medical and Chirurgical Faculty of Maryland; on the staff of the Memorial Hospital; aged 64; died, July 14, of coronary sclerosis and diabetes mellitus.

Stuckey Fleetwood McIntosh * Tucson, Ariz.; Tulane University of Louisiana School of Medicine, New Orleans, 1921; at one time secretary of the Chattanooga and Hamilton County (Tenn.) Medical Society; aged 44; died, July 24, at Van Horn, Texas, of heart disease.

Thomas Theodore Sawyer * Kansas City, Mo.; University Medical College of Kansas City, 1907; veteran of the Spanish-American and World wars; aged 59; died, July 25, in the Veterans Administration, Excelsior Springs, of chronic nephritis and hypertension.

Christopher Tuttle Croddy, Portland, Ore.; Rush Medical College, Chicago, 1897; member of the Oregon State Medical Society; aged 75; died, June 26, of angina pectoris, arteriosclerosis and hemiplegia.

Henry Ferrell Carman, Butte, Mont.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; aged 63; died, July 24, in Wise River, of cerebral hemorrhage.

William Harry Hawley * College Corner, Ohio; Miami Medical College, Cincinnati, 1885; member of the Indiana State Medical Association; formerly member of the school board; aged 80; died, July 6.

Oscar Clyde Page, Brodnax, Va.; University College of Medicine, Richmond, 1911; member of the Medical Society of Virginia; served during the World War; aged 53; died, July 1, of heart disease.

James Everett Pierpoint, Skidmore, Mo.; Ensworth Medical College, St. Joseph, 1899; member of the Missouri State Medical Association; aged 69; died, July 14, of coronary occlusion.

Leonard S. Krauss, Middletown, Ohio; Ohio Medical University, Columbus, 1895; aged 85; died, July 16, of arteriosclerosis, Parkinson's disease and heart disease.

Dwight Stanley Whittemore, Brockton, Mass.; Boston University School of Medicine, 1887; aged 74; died, June 25, of cerebral thrombosis and arteriosclerosis.

Peter L. Benthack, Chadron, Neb.; Kansas City (Mo.) Homeopathic Medical College, 1899; aged 70; died, June 12, of epithelioma of the lower lip.

Elizabeth Pruin Hofma, Grand Haven, Mich.; Woman's Medical College, Chicago, 1891; aged 78; died, July 2, of myocarditis and arteriosclerosis.

Samuel Houston McMahan, De Ridder, La.; Kentucky School of Medicine, Louisville, 1898; aged 74; died, July 3, of encephalitis.

Daniel Keyworth Cowley, Granby, Que., Canada; McGill University Faculty of Medicine, Montreal, 1880; aged 81; died, July 10.

John R. Holsclaw, Shepherdsville, Ky.; Louisville (Ky.) Medical College, 1875; aged 87; died, June 30, of chronic nephritis.

George L. Hines, Williamsburg, Ohio; Medical College of Ohio, Cincinnati, 1882; aged 81; died, July 15, of senile dementia.

George G. Kreeger, Richmond, Kan.; Kansas City (Mo.) Medical College, 1895; aged 65; died, July 11, of coronary sclerosis.

Thomas G. Howe, Atlanta, Texas; Memphis (Tenn.) Hospital Medical College, 1893; aged 83; died in July of senility.

Jacob Marcus, Boston; Tufts College Medical School, Boston, 1912, aged 53; died, June 22, of hypertension.

Correspondence

CALCIUM METABOLISM AND TEETH

To the Editor:—While there are some problems pertaining to dental caries which remain unsolved, there are innumerable well established facts relating to it which are widely known and generally accepted. Dr. Schour in his article on calcium metabolism and the teeth in *THE JOURNAL* (March 19, p. 870), logically and dispassionately stated these facts and fairly summarized the present status of dental caries. While it is not meant that his studies are complete or final, the chemicoparasitic theory to which he subscribes will not be modified and the data on which he bases his conclusions will not be disproved. It was, therefore, regrettable and confusing that an article of such outstanding merit should have been questioned by Dr. McCall (*THE JOURNAL*, July 23, p. 338), particularly since the criticisms were based on so little and as yet controversial evidence.

Since the days of Miller it has been almost universally accepted among scientists that decay begins externally, that the enamel is entirely passive in the process, and that the disease is caused by acids liberated by the bacterial fermentation of carbohydrates.

Periodically during the last decade, certain individuals have made many attempts, unfortunately not based on adequate scientific evidence, to revive the discarded humoral and vital theories of decay. These investigators have postulated that the enamel, through its organic matrix and lamellae, remains under metabolic and physiologic influences throughout life and therefore is not only subject to variations in its resistance to dental caries but exhibits the ability to defend and repair itself actively. The fact that devitalized and normal teeth, as far as the enamel at least is concerned, react pathologically in an identical manner and likewise and to the same extent exhibit susceptibility or immunity to dental caries, together with the fact that there is a reciprocal relationship between tooth density, permeability and caries, should be sufficient evidence to disprove the claims of those who contend that metabolism occurs in formed enamel and that on the efficiency of this process depends the incidence and progress of decay.

More recently the vital humoralists have postulated that alterations of systemic metabolism, secondary to the ingestion of modern food, cause a change in the chemical nature of the saliva, which by altering the local environment permits enamel decalcification and the development of caries. The main evidence on which Dr. McCall takes exception to the article by Schour is predicated on this as yet wholly unproved assumption: that there is a chemical difference between the salivas of caries immune and caries susceptible individuals. To date there has been no satisfactory evidence submitted that there is any difference in chemical composition of the clean saliva of the two groups. On the contrary, the evidence overwhelmingly favors the view that the saliva as it enters the mouth is chemically if not immunologically identical in the two groups.

I disagree with Dr. McCall's contention that pregnancy may influence the development of caries and that hypoplastic enamel is more susceptible to caries than normal enamel. From a review of Dr. McCall's work I have been unable to find any evidence which would justify the conclusion that "evidence is accumulating to show that at any time of life the general metabolism affects the teeth and largely determines whether or not they will decay."

In view of the already widespread acceptance of Schour's views it is somewhat anachronistic and unnecessarily alarming to contend that Schour's "conclusions might, if accepted, have possible unfortunate effects on medical practice." To date no satisfactory evidence has been submitted which would tend to

favor the belief that metabolism occurs in formed enamel; therefore, in view of the really large amount of evidence to the contrary the burden of proof that it does occur must continue, of course, to rest with the exponents of the vital theories.

While it is remotely possible that the theory of chemico-parasitism may eventually prove to be inadequate to explain certain facts pertaining to dental caries, it is apparent that the contentions and evidence presented by McCall do not seriously challenge, much less demand the modification of, Miller's theory of decay.

JULIAN AMBROSE, D.D.S., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DEATH RATE AND INCOME

To the Editor:—Have you any statistics relative to the comparative death rate in the lower income group (up to \$2,000 or \$2,500) as it is at present and as it was twenty years ago? The statement was made recently that the death rate had declined in the upper income group on account of the better available medical facilities but that the death rate in the lower group was as high as ever.

ROBERT C. JAMIESON, M.D., Detroit.

ANSWER.—No studies comparing the death rates in the lower income classes twenty years ago with the death rates today have been found. Prior to 1930 there were no studies of mortality data according to occupation, and no statistics have been compiled on mortality rates by income classes, except for a few special studies of individual causes of death.

Mortality statistics from the Bureau of the Census show that the death rate has decreased from 15.0 per thousand in 1910 to 10.9 per thousand in 1935, or a decrease of 27.3 per cent. If the upper limit of the low income group is taken as \$2,500, nearly 20,000,000 families, or 71 per cent of all families in the United States, would belong to this group (America's Capacity to Consume, Brookings Institution). Consequently the decline in the death rate during the twenty-five year period from 1910 to 1935 could not be accounted for by a decrease in mortality rate for the persons in the income group above \$2,500 alone.

Likewise the Metropolitan Life Insurance Company, in a study of the mortality rate among its industrial policyholders, showed a decline of 35.8 per cent in the mortality rate during the period from 1911 to 1938 (Statistical Bulletin, Metropolitan Life Insurance Company, January 1938). The industrial policyholders of the Metropolitan were largely persons in the lower income brackets of the urban population.

From the foregoing it appears rather certain that the death rate in the lower income group has been steadily decreasing during the past twenty years.

A special study of mortality statistics according to occupation was made for ten states which in a certain way indicates the mortality rate according to the economic status of the majority in the occupational group (Death Rates by Occupation, by J. S. Whitney, based on United States Census Bureau data for 1930). For example, the mortality rate for professional men in 1930 was 7.0 per thousand, while for unskilled workers it was 13.1 per thousand.

No similar study has been made since to show whether the mortality in the occupational groups with a relatively high average economic status is declining faster than the mortality rate for occupational groups with a lower economic status. Furthermore, mortality studies according to occupational groups do not accurately show the mortality according to economic status, because the occupational hazards have a greater effect on the mortality rate than the differences in the standards of living; that is to say, a group of unskilled workers with an average income of \$100 a month would be more likely to have a higher death rate than a group of professional workers with an average income of \$100 a month, chiefly because of the hazards of the occupations followed by unskilled workers.

The statement that the death rate in the upper income group is lower on account of the better available medical facilities is inaccurate because many other factors are involved. As an example, *Public Health Reports* for Sept. 2, 1934, shows the results of an experiment in Liverpool, England, where the death rate from all causes for a certain slum area was reduced from 37.0 per thousand to 26.6 per thousand after the area was rebuilt with better homes and improved sanitation; with few exceptions the same population remained in the area. Likewise, agricultural workers have the lowest mortality rate of any occupational group, which indicates that occupational conditions and the standard of living are important factors in reducing mortality.

The United States Public Health Service has made a great many sample studies of morbidity and mortality in relation to economic status. In general, these studies indicate that higher illness and mortality rates among the poor are caused primarily by factors such as crowded housing conditions, lack of adequate food and clothing, and occupational hazards. The availability of medical care is also a factor.

ASCENDING PARALYSIS AND POSSIBLE SPINAL CORD COMPRESSION

To the Editor:—A man aged 48, whose present complaint is increasing paralysis of the spastic type for the last six months, has entirely lost the action of his legs. He can move both arms slightly and when he does so there is a decided tremor. Knee, ankle, biceps, triceps are all hyperactive and equal. Ankle clonus is bilateral; there is a suggestive right Babinski; the Hoffmann thumb sign is present in both hands; the abdominals are present, the cremasteric is decreased; vibration sense is normal; likewise pain, temperature and tactile sense are normal. There is no slurring of speech; the eye grounds are normal; there is no bitemporal pallor or nystagmus; the facial expressions are normal; there is no cranial nerve involvement, headache, double vision or difficulty in swallowing. X-ray examination of the skull shows questionable early calcification of the pituitary; x-ray examination of the cervical spine shows a normal condition. The blood count, red and white, is within normal limits; the blood and spinal Wassermann reactions are negative. The spinal fluid cell count shows 2 cells; sugar (spinal fluid) 75; protein, 57. The patient is clear mentally. There is no history of injury. Occasionally there is a rise in temperature of 1 degree. The urine is essentially normal. The paralysis began with the lower extremities and is progressing upward. A neurologist is as puzzled as I am.

M.D., N. Y.

ANSWER:—Increasing spastic paralysis in a man of 48, beginning in the legs and ultimately involving the arms, is suggestive of compression of the spinal cord. The facts, as given, indicate that this possibility has not been entirely ruled out. The level of the lesion is at least as high as the fifth cervical segment and the practical question arises as to whether or not evidence is present of disease of the first four cervical vertebrae. Although the roentgenograms of the cervical spine are said to show a normal condition, particular care should be directed toward a complete examination of these four vertebrae—not by any means an easy task. Tuberculous osteitis, secondary carcinoma or other neoplasms such as sarcoma, myeloma or lymphoblastoma are easily overlooked unless the roentgenograms are exceptionally good. There is evidence, moreover, of a partial block in the spinal fluid in that the total protein is 57 mg., somewhat higher than the normal limit. Unfortunately the record does not state anything with regard to the hydrodynamics of the cerebrospinal fluid, particularly the Queckenstedt test. In high spinal cord tumors this test is not of as much value as in those lower down. Nevertheless, evidence along these lines should be sought for. Of particular value in an obscure case would be a combined cistern and lumbar puncture, with a record of both responses to jugular compression and also a comparison of the amount of protein from both loci. If any signs of block should be found, an attempt should be made to visualize the exact level of the lesion, and possibly its nature, by the injection of iodized oil into the cistern, allowing it to run down in the spinal subarachnoid space. By such an examination, tumor or adhesive arachnoiditis might be disclosed. Pachymeningitis, moreover, in this region is certainly to be considered. It does not necessarily need to be on a syphilitic basis. Should evidence for a block in the cerebrospinal fluid be obtained by examinations, laminectomy with exposure of the area would be the treatment of choice.

Without sensory changes or disturbance of the sphincters, intramedullary cord tumor is unlikely, nor would one expect to find an intrinsic degenerative disease like syringomyelia. The lack of any involvement of the cranial nerves, plus the presence of the abdominal reflexes, along with the patient's age, make a diagnosis of multiple sclerosis unlikely.

It is therefore clear that, before a definite diagnosis can be made, the patient needs additional examinations. Such exami-

nations as the combined puncture, the injection of iodized oil and the reading of the results by the radiologist require a good deal of skill and should not be undertaken unless a thorough understanding of the value of these examinations is available. In view of the patient's progressive paralysis, such examinations are entirely justified and operation should not be overlooked as an important means of treatment should the examinations disclose a definite compression of the spinal cord.

EHLERS-DANLOS SYNDROME

To the Editor:—Please send information concerning the Ehlers-Danlos syndrome: symptoms and treatment, if any.

ERNEST B. HANAN, M.D., Bolivar, Mo.

ANSWER:—The Ehlers-Danlos syndrome is congenital and of rare occurrence. Its subjects are not unusually objects of curiosity and are therefore exploited in cheap museums and sideshows.

There are essentially three parts to the syndrome. The skin is abnormally elastic, so that it may be pulled out to excessive distances. The favorite sites to elicit this increased elasticity are at the elbows and knees. The skin may snap back into place like a rubber band after it is pulled. Other times there is a more gradual resumption of the original outline of the skin. Noteworthy histologic changes of the skin seen in the hyperelastic regions are tortuosity of the blood vessels and undulations and increase in the elastic elements. The second cardinal feature of this syndrome is the overextensibility of the joints, especially at the base of the thumb. Finally the skin is easily injured to form thin atrophic scars. These occur most frequently about joints, especially at the elbows and knees. The type of scarring is characteristic and is the most commonly encountered sign of the triad. It is more frequent that individual signs occur alone or in combination with one other. More rarely the full syndrome of three signs appears.

Several congenital anomalies have been associated and confused with the Ehlers-Danlos syndrome. Dermatitis, in which there are loose aprons of skin, is not to be identified with this syndrome. Related to it but not identical is the dystrophic variety of epidermolysis bullosa. The connection of Recklinghausen's disease and the Ehlers-Danlos syndrome has been discussed in the literature.

There is no suggested therapy. It is a permanent developmental anomaly.

TETANUS ANTITOXIN OR CORONARY THROMBOSIS AS CAUSE OF DEATH

To the Editor:—A patient cut one finger of one hand on a nail, Feb. 14, 1938. On the same day he was given first aid treatment and 1,500 units of tetanus antitoxin, first having been tested intradermally. Approximately one week later he had an attack of syncope, associated with precordial pain, weakness, dyspnea and loss of consciousness. At this time the family noticed that he had a generalized erythematous rash and he was taken to a hospital where he was told that he had a serum reaction. The man continued to work and approximately one week later had a second attack, when he complained of pain in his chest followed by a rapid loss of consciousness. He died in a few minutes. The only abnormalities at the autopsy were a moderate coronary sclerosis and a recent myocardial infarct, which was along the course of one of the branches of the left coronary artery. On microscopic examination it was found that the infarct had occurred from ten to fourteen days before death. The pathologist reported that the man died of coronary spasm, which was sufficient to cause death because of the already damaged infarcted left ventricle, that there was a definite connection between the tetanus antitoxin and the cardiac condition and symptoms and that he believed the tetanus antitoxin was definitely a contributory factor in the death of this man. I have talked with cardiologists who do not believe that the tetanus antitoxin was a contributing factor. Please give your opinion, with reference to the literature if there is any.

M.D., Texas.

ANSWER:—A man, age unstated, had an attack of syncope, precordial pain and other symptoms, which was followed by a second and similar but fatal attack about one week later. Coronary sclerosis and myocardial infarction were demonstrated and evidently it concerned a fairly typical case of fatal coronary disease. The question is raised whether an injection of tetanus antitoxin had exercised a determining effect on the course of events. The statement mentions that an erythematous rash was present when the first heart attack came on about one week after the antitoxin was given. In view of the great variety of conditions under which a heart attack set in it is purely speculative whether the alleged serum reaction had any part in the first attack in this case. That the serum reaction had any direct part in the second and fatal attack seems quite unlikely,

b. cause it occurred a week or so after the reaction. There is no other evidence available except the apparent coincidence of the serum reaction and the first attack to support the statement that "the tetanus antitoxin was definitely a contributing factor in the death" of the patient.

AREA FOR INJECTION OF PERTUSSIS VACCINE

To the Editor:—Why is the Sauer pertussis vaccine given in the arm alone? Is there some reason for injecting the vaccine in different areas of the arm or would any subcutaneous injection be all right?

CLARENCE M. O'HORA, M.D., Beaver Dam, Wis.

ANSWER:—In 1925 Madsen reported on the injection of *Haemophilus pertussis* vaccine containing 10,000,000,000 bacilli per cubic centimeter, a total dose of 2.2 cc. (0.5, 0.7 and 1 cc. at three day intervals). This dose usually failed as an immunizing agent, but Danish clinicians and health officers observed a milder course and fewer deaths in patients who had had the vaccine. They believed that their best results occurred in those who had a transient local reaction at the time of injection. In his vaccination against whooping cough, Sauer since 1928 has used for children under 2 years of age a total dose of 8 cc. (2, 3 and 3 cc. at weekly intervals), a total of 80,000,000,000 bacilli. He believes that a better immunity response occurs when the injections are given just under the skin. The freshly isolated cultures are grown on human blood mediums to exclude anaphylaxis and sensitization due to alien proteins.

The upper parts of the arms are the logical site for the superficial injection of such quantities of concentrated vaccine. The arms were probably chosen because the desired local reaction (immediate blanching, subsequent erythema) would cause the least inconvenience there. It is less likely to be scratched than if given on the trunk. The buttocks would entail unnecessary hazards, because of the danger of abscess from fecal contamination or excoriated skin from ammoniacal diapers.

Infection of the upper arms will not occur if the syringe and needle are sterilized by heat (oven at 250 F. for one hour, or boiling), vial cap and site thoroughly cleansed with ethyl (not "rubbing") alcohol. Wet dressings should not be applied for local redness.

PERSISTENT LEUKOPENIA

To the Editor:—Have there ever been reported in the literature such conditions as anomalies of the hemopoietic system in which the normal white cell count is extremely low? A man aged 23 on repeated examinations is found to have a white cell count of 1,500, the lowest count being 1,100 and the highest 2,000. The only significance of the differential counts is the finding of an increased number of band forms, varying from 11 to 34. The other components of the blood have been normal. The patient feels well and repeated physical examinations in the last two months have revealed nothing of significance to lead one to suspect leukemia or a true agranulocytosis. The patient was admitted to the hospital because of the low count found on a routine check-up.

M.D., Rhode Island.

ANSWER:—There occur occasionally physiologic leukopenic states lasting for years in persons in whom no primary bone marrow or secondary causative tissue or organ disorder can be found (Doan, C. A.: *The Neutropenic State*, *THE JOURNAL*, July 16, 1932, p. 194). In such cases intercurrent infections are accompanied by adequate granulocytic leukocytoses; the duration and severity of such illnesses is no greater than in those cases in which an average interim total white cell count of between 5,000 and 10,000 is shown, and bone marrow studies reflect no disturbance in the normal myeloid-erythroid ratio or in the physiologic maturation pattern of the myelocytes. Such cases reported in the medical literature, however, usually have shown a total white count maintained between 2,000 and 3,500 with normal differential white cell relationships, both qualitatively and quantitatively.

When the total white count remains persistently below 2,000 and on repeated observations may even occasionally fall below 1,000, without other readily detected signs or symptoms, as in the case cited, one must seriously consider an early Banti's syndrome. The first evidence of this disease entity may be a profound asymptomatic leukopenia. Sooner or later the spleen will become palpable and one or more of the usual liver function tests, including the bromsulphalein dye, the galactose tolerance and the hippuric acid excretion tests, will reflect hepatic damage. The bone marrow shows no inhibition or diminution of normal hemopoiesis and unless and until gastrointestinal hemorrhage occurs, occult or gross, there will be no anemia and no significant platelet changes. The leukopenia would appear to depend on a specific splenic sequestration of leukocytes because following successful splenectomy in such cases the total white count again becomes normal. There are no pathognomonic tests or

physical signs in the establishment of Banti's syndrome early. The diagnosis must be made by eliminating all other possible mechanisms for the leukopenia, and the alert physician may occasionally advise prompt splenectomy in order to avert a massive esophageal hemorrhage, which so often is the first sign of the far advanced disease. Successful splenectomy in this condition depends on early diagnosis before perisplenic adhesions and venous dilations make removal of the spleen impossible.

Leukopenia rarely, if ever, is the initial blood finding in incipient hypoplastic or aplastic anemia. When present, it is distinctly a granulopenic leukopenia and practically always is preceded or accompanied by a more or less marked thrombocytopenia or/and anemia.

True agranulocytosis also is reflected by a granulopenic white count, with absolute marrow myelopenia and immaturity, and usually is followed promptly by characteristic clinical symptoms.

Aleukemic leukemia likewise is seldom asymptomatic or without physical signs, and the quality and relative disproportionate increase of the leukemic cells should be diagnostic.

DIAGNOSIS IN SPASTIC ATAXIA

To the Editor:—A man aged 65 had pneumonia six years ago. During his convalescence he noticed stiffness, numbness and prickling sensations of his legs and feet without pain. He has had difficulty since in walking in the dark, stumbling easily, and the leg symptoms have persisted. He now has pain in the legs and his hands feel as if they were asleep. He complains of tightness around the lower part of the abdomen, beltlike in character. He weighs 172 pounds (78 Kg.) and has a blood pressure of 174/70 and a regular pulse of 100. The Romberg sign is present. He has loss of vibratory sense from the waist down. The knee jerks are slightly exaggerated; the Babinski reflex is present; abdominal reflexes are lost. There is no nystagmus. The blood count reveals 4,180,000 erythrocytes, 7,800 leukocytes, a normal differential and hemoglobin of 13 Gm. The blood and spinal fluid Wassermann, Kline and Kahn reactions are negative. There is a slight increase of globulin in the spinal fluid. The colloidal gold curve is 1112321000. There are no other symptoms or positive physical signs. Do you agree that the most probable diagnosis is subacute combined sclerosis of the spinal cord? With this blood picture, without benefit of gastric analysis, can I say that he has no primary anemia? With no history of syphilis or of observations other than those given, can I say that he does not have syphilis? What may I offer him in the way of prognosis and therapy? How should the colloidal gold curve be interpreted?

REID P. JOYCE, M.D., Ashland, Ohio.

ANSWER:—The patient has the signs and symptoms of spastic ataxia due to involvement of the posterior and lateral columns of the spinal cord (thoracic cord?). The most probable causes of this condition may be (1) pernicious anemia resulting in subacute combined cord degeneration; (2) cerebrospinal sclerosis (arteriosclerotic); (3) pneumonia; (4) cord tumor; (5) avitaminosis. To make a diagnosis of subacute combined sclerosis of the spinal cord one should find achylia gastrica (no free acid in the stomach contents). If achylia gastrica is not found, the most likely diagnosis is a pneumonic myelitis. One should do a careful manometric study of the spinal fluid to rule out a block due to a tumor. The second question cannot be answered. In 30 per cent of cases of subacute combined cord degeneration the blood picture is normal. In six years, however, there should have been a change in the blood picture if one is dealing with a pernicious anemia, unless the patient is being treated with large doses of liver. From the evidence submitted one can be fairly confident that the patient does not have syphilis. The prognosis is doubtful. The patient should be placed at absolute bed rest for a period of six to eight weeks and large doses of liver with vitamins A, B₂ and G given three times weekly by intramuscular injection. Reeducation exercises are suggested for the sensory ataxia. The colloidal gold curve is not significant of any condition. It should be considered as an atypical normal.

TREATMENT OF CONGENITAL CLUBFOOT

To the Editor:—What is the best therapy for congenital clubfoot (rigid contracted arch)? What percentage of cures are effected when the usual surgical procedures are employed?

ROBERT MONFORT, M.D., Onaway, Mich.

ANSWER:—Treatment for congenital clubfoot depends on the type of deformity, which may be varus, valgus, calcaneus, equinus or a combination of two or more of these, and also on the age of the child and the methods of treatment which have been used previously. Since the patient concerned is said to have a rigidly contracted arch, it may be safely assumed that it is not a newborn infant. Approximately 75 per cent of clubfoot deformities are of the talipes equinovarus type. When early correction has not been successful or the condition has been neglected until the deformity has become rigidly fixed with a

contracted arch, an operation is indicated. This may include section of the flexor hallucis longus tendon, posterior capsulotomy of the ankle, lengthening of the achilles tendon, or section of the adductor brevis tendon and of the plantar fascia near its insertion into the os calcis. These are the structures, either static or dynamic, which are responsible for maintenance or recurrence of the deformity. After these operative procedures the foot should be manipulated while the patient is still under the anesthetic and a cast applied to maintain a position of over-correction. In some instances the number of operative procedures may be less than those mentioned and in other cases more. For the patient 6 years or younger, this course of treatment may be found adequate in a reasonably high percentage of cases. For patients more than 6 years of age, one has to consider the advisability of arthrodesis of some of the proximal tarsal joints. This may be indicated when there is severe deformity of the bones of the foot because of long continued malposition.

The surgeon should constantly keep in mind the fact that, while it may not be difficult to manipulate and correct the position of a clubfoot, the factors of muscle imbalance and ligament contractures must be treated in order to prevent prompt recurrence with even more serious deformity after the restraint of the cast has been removed.

Some authors have stated that 60 per cent of these cases will recur when only manipulation and cast are used in the treatment.

ESTIMATION OF SPINAL FLUID PROTEIN

To the Editor:—What is the best technic for estimating the total protein in the spinal fluid? ROBERT M. HARBIN JR., M.D., Rome, Ga.

ANSWER.—The amount of protein present in normal cerebrospinal fluid is so small (under 0.1 per cent) that its accurate estimation is a matter of some difficulty. Several different procedures may be followed: 1. The total nitrogen, and nonprotein nitrogen after Folin-Wu tungstic acid precipitation, may be determined in the spinal fluid by the micro Kjeldahl method, the difference between the two determinations taken as representing the protein nitrogen and multiplied by the factor 6.25. 2. The protein may be precipitated by tungstic acid and the amount of this precipitate estimated by either (a) the micro Kjeldahl nitrogen estimation or (b) the use of Folin's tyrosine reagent (Ling, S. M.: *J. Biol. Chem.* 69:397 [Aug.] 1926) and the amount of protein calculated by employing suitable factors [(a) 6.25 and (b) 19.1]. 3. Or more simply by precipitating the protein with some reagent such as sulfosalicylic acid and determining the amount of this precipitate nephelometrically or turbidimetrically. The last procedure was employed by Denis and Ayer (*Arch. Int. Med.* 26:436 [Oct.] 1920) with satisfactory results and has since been used by many workers. Marjorie R. Mattice (Chemical Procedures for Clinical Laboratories, Philadelphia, Lea & Febiger, 1936, p. 387) states that she has found this method to check with the Kjeldahl procedure. The Dennis-Ayer method would appear to be the simplest satisfactory method of estimating spinal fluid protein.

SECOND COURSE OF MALARIA FOR DEMENTIA PARALYTICA

To the Editor:—The members of the staff of the hospital with which I am connected have been having some arguments of late as to the efficacy of repeating malarial therapy in dementia paralytica. Some claim that it is useless to give it more than once and others that it should be repeated. What is your opinion? M.D., Indiana.

ANSWER.—The reports which appeared in the literature for several years after Wagner von Jauregg suggested the use of malaria indicated that a second course of malaria would occasionally produce satisfactory clinical results when the first course had been unsuccessful. However, subsequent experience has not substantiated this observation and it is now generally accepted that the second malarial course will not be more successful than the first.

It is usually impossible to produce a second febrile course from reinoculation with malaria that will produce more than one or two attacks of fever, because these patients tend to arrest the malaria spontaneously. Although the blood may show *Plasmodium vivax* following inoculation the second time, the chills and fever do not develop. If a patient does not derive

clinical or serologic benefit from a course of malaria, it is of more advantage to use one of the fever producing machines for the second fever course rather than to attempt to use the malaria a second time. Irrespective of the type of fever therapy employed, the use of arsphenamine and a bismuth compound or tryparsamide and a bismuth compound is indicated after the fever course.

CAR SICKNESS: PAROXYSMAL LABYRINTHINE DISEASE OR EPILEPSY

To the Editor:—A boy aged 12 is subject to car sickness, depending on the anxiety with which he travels to a certain destination by automobile or trolley car. He becomes pale and nauseated and is slightly uncomfortable even after riding merely a half hour. He is not so likely to become car sick while riding in an omnibus. Physical and otologic examinations reveal nothing to account for this. His eyes have recently been refracted and he is wearing proper glasses. Casual riding on a bicycle has not given him any trouble. Is there any danger from a fall if bicycle riding causes a feeling similar to car sickness? I myself have not known of such an instance, yet a neurologist has warned the boy against bicycle riding. On the other hand, it is likely that bicycling would accustom a boy to traveling so that car sickness would be mitigated when he rides in an automobile or trolley car? M.D., Pennsylvania.

ANSWER.—The diagnosis appears to be paroxysmal labyrinthine disease. In this condition the only objective finding is usually an irritable labyrinth. If this is the case there is no danger from a fall while riding a bicycle. One must be sure that one is not dealing with epilepsy. That is why the neurologist in all probability advised against riding a bicycle. It is suggested that this boy be placed on a salt free diet and given from 1.3 to 1.6 Gm. (20 to 25 grains) of ammonium chloride in a capsule three or four times daily for a period of ten days or two weeks. This condition is analogous to sea sickness, air sickness and elevator sickness.

OAK BALM SUPPOSITORIES

To the Editor:—What is the present status of the Oak Balm (Hager Company, South Bend, Ind.)?

ROBERT MONTFORT, M.D., Onaway, Mich.

ANSWER.—No analysis has been made of "Oak Balm" by the American Medical Association. Some years ago the state chemists of North Dakota analyzed Oak Balm and reported that these suppositories were composed chiefly of boric acid and alum, in a cacao base. The chemists added that "tannin was not detected, therefore no oak constituent was present." As there is nothing to prevent "patent medicine" exploiters from changing the composition of their products overnight, we are unable to state whether the ingredients given above represent the present composition of this nostrum.

LEFT HANDEDNESS IN CHILD

To the Editor:—What is the present status of treatment of left-handedness in a child? A boy aged 3 has been using his left hand in picking up and holding objects and now uses this hand to eat with almost exclusively. His use of the right hand seems awkward. Should any attempt be made to correct this? If so, what is the best procedure? M.D., Pennsylvania.

ANSWER.—It is considered unwise to attempt to coerce a distinctly left-handed child to use his right hand as the dominant one. There is some justification in making an exception in training the child to use the right hand in eating, since this avoids later social discomfort. No measures more energetic than persistent encouragement in the use of the right hand for eating are justified.

TRAUMA AND PRIAPISM

To the Editor:—I have a case of priapism which I believe is on the basis of trauma and thrombophlebitis of the corpora cavernosa and spongiosum. The patient was injured about two weeks ago while attempting intercourse while under the influence of alcohol. The priapism came on at once and has existed up to the present. Neurologic consultation has ruled out cord lesion, the Kahn reaction is negative, and blood studies rule out a leukemia. Free use of sedatives and narcotics have failed to influence the condition, as have spinal anesthesia, high voltage roentgen therapy and diathermy. The therapeutic measure of greatest value to date has been sitz baths. I would appreciate any suggestions as to the diagnosis or treatment. M.D., Pennsylvania.

ANSWER.—There is no doubt from the history of the case that it belongs to the traumatic group. The treatment should be incisions under absolute asepsis to remove any blood clots and to allow free drainage of the exudate. The incisions should be made into the most turgid portions of the penis.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 20-22. Sec., Dr. J. N. Baker, 517 Dexter Ave., Montgomery.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of *Special Boards* were published in THE JOURNAL, September 24, page 1235.

Texas June Examination

Dr. T. J. Crowe, secretary, Texas State Board of Medical Examiners, reports the written examination held at San Antonio, June 20-22, 1938. The examination covered twelve subjects and included 120 questions. An average of 75 per cent was required to pass. One hundred and ninety-two candidates were examined, 176 of whom passed and sixteen failed. The following schools were represented:

| School | PASSED | Year Grad. | Per Cent |

Book Notices

Industrial Surgery: Principles, Problems and Practice. By Willis W. Lasher, M.D., F.A.C.S., Assistant Professor of Traumatic Surgery, New York Post-Graduate Medical School, Columbia University, New York. Cloth. Price, \$6. Pp. 452, with 193 illustrations. New York: Paul B. Hoeber, Inc., 1938.

The wide scope in industrial surgery, which is only one department of industrial medical practice, is illustrated by the table of contents in this new work. The author states that there is scarcely a part of the human body which is not subject to the effects of trauma nor are there any tissues which have not become secondarily invaded by the complications associated with injury. Lasher's wide experience in industrial accidents serves as a basis for a comprehensive review of this field of surgery, with excellent chapters on general surgical considerations including a discussion of embryology, histology, physiology, biochemistry and surgical pathology. In developing his book the author has confined himself to his actual experiences and has not attempted to bridge over omissions by referring to other sources. In the preface the philosophy of industrial surgery is discussed and a sound approach to the various problems encountered is indicated which is well carried out throughout the text. The book includes chapters on the organization of medical departments in industry, an appendix describing various appliances used by the author, and a fairly complete bibliography. It should prove a valuable working manual in this field.

Endogene Endokrinotherapie in der Gynäkologie: Ätiologie und Behandlung des Karzinoms. Von Dr. Jules Samuels, Chirurg-Frauenarzt, Leiter der Einrichtung für Kurzwellentherapie, Amsterdam. Paper. Price, 4.90 florins. Pp. 182, with 32 illustrations. Leiden: A. W. Sijthoff's Uitgeversmaatschappij N. V., 1938.

During the last two years the author of this book has written three books and twenty-five articles, and the latter were published in Netherlands, German, French, British, American, Italian and Japanese journals. These books and articles dealt almost exclusively with one subject. The author devised an instrument which he calls a cycloscope, the essential part of which is a spectroscope. He uses the instrument to study the endocrine glands and plots curves which he calls cyclograms. He makes many remarkable statements which have not as yet been substantiated by others. Some of these contentions are the following: Women ovulate two or three times a month and therefore can become pregnant this often during each intermenstrual interval. The author can tell by means of his instrument exactly which endocrine gland has a disturbed function and whether there is excessive or diminished hormonal activity of this gland. Likewise he can tell whether the dysfunction can be remedied or not. He can cure heretofore incurable endocrine disturbances by means of short wave therapy. He can successfully treat a dysfunctioning pituitary gland and in this way indirectly treat the mesencephalon and diencephalon. Duodenal and gastric ulcers have a central origin and the dysfunctioning of the stomach center is caused by a gonadotropic hyperpituitarism. Climacteric disturbances are due to dysfunctioning of the diencephalon under the influence of overproduction of gonadotropic hormone. The toxemias of pregnancy are due to hyperproduction of placental hormone, especially the placental estrogenic hormone. Many cases of genuine liver and kidney disease have a hormonal origin, which

consists of a hyperfunction of the gonadotropic hormones the result of a gonadotropic hyperpituitarism. Habitual abortion is due to hypoproduction of placental hormone, thereby enabling its antagonist, the posterior pituitary hormone, to act. Likewise hydatid moles have their origin in hypoproduction of placental estrogenic hormone. In cases of benign tumors there is always a gonadotropic hyperpituitarism and in cases of malignant tumors there is a thyrotropic hyperpituitarism. Therefore the endocrine electrodiagram is a helpful means of differentiating a benign from a malignant tumor. In the management of tumors, the pituitary must be treated. The most efficient way of treating carcinoma endocrinologically is to apply short wave therapy to the pituitary and to the gonads except in cases in which the gonads are already inactive. In such cases, treatment of the pituitary alone suffices. The author ends his book with the statement that the cycloscope is an indispensable instrument. However, thus far no one has published any confirmatory evidence in support of the author's contentions. In one large university in this country the cycloscope has failed completely to substantiate what Samuels claims for it.

The Synovial Membrane and the Synovial Fluid with Special Reference to Arthritis and Injuries of the Joints. By David H. Kling, M.D., Assistant Professor of Orthopedic Surgery and Chief of Arthritis Clinic, White Memorial Hospital, Los Angeles, California. Cloth. Price \$3. Pp. 299, with 80 illustrations. Los Angeles: Medical Press, 1938.

Few medical schools give instruction on the diagnostic and prognostic value of synovial fluid, in contrast to the emphasis placed on the cerebrospinal fluid. With the publication of Kling's readable monograph there is no longer any excuse for omitting consideration of the synovial fluid as actually and potentially as important as the spinal fluid. The present knowledge of the histogenesis, morphology and functions of the synovial membrane and its physiology are ably reviewed. The author has himself been one of the principal investigators in the field. Also the pathologic alterations of the synovial membrane in disease are discussed. This consideration of the synovial membrane is a necessary preliminary to accurate knowledge of the origin and function of synovial fluid and meaning of changes in this fluid as a reflection of the pathologic conditions. The monograph closes with four brief chapters on the clinical value of the aspiration of joint effusions and the technic and value of aspiration as a diagnostic procedure either alone or combined with injection of liquids and gases and their therapeutic usefulness. There are still many features of the synovial membrane and synovial fluid the exact significance of which is not yet determined. These holes in knowledge and interpretation are, however, rapidly filling, as can be determined by the number of recent references contained in the book. Furthermore the deficiencies in knowledge are not so large as to discourage the more widespread adoption of articular aspirations and further clinical pathologic studies. This monograph can be considered the most authoritative book in its field available today and it is hoped that the author will revise it at frequent intervals, since progress is so rapid that many of the hiatuses in knowledge may not remain unfilled for long.

Diseases of the Thyroid, Parathyroids and Thymus. By André Crotti, M.D., F.A.C.S., LL.D., Surgical Assistant at Roux's Clinic, Lausanne, Switzerland. Third edition. Leather. Price, \$20. Pp. 1,229, with 301 illustrations. Philadelphia: Lea & Febiger, 1938.

This edition closely resembles the previous edition in the luxuriousness of the makeup and the inevitable ribbon marker. The contents of the book have been enlarged by the addition of a chapter on the fundamental physiology and pathology of the parathyroid glands. The author freely injects his own ideas about the function of these glands and their various relationships to other organs and tissues of the body. Many of his conclusions are empirical and abrupt, presented in a staccato manner without sufficient discussion. Others are long and involved, fortified with case histories and reports of experimental studies; all statements seem overwhelmingly and equally positive. Endemic goiter is attributed to a fungus found in cabbage. The author cites some experimental proof of this according to his observations and claims to have fulfilled Koch's postulates. There is a great deal of information in this book which could have been

digested and presented in a much briefer content. The bibliography is complete but is presented at the back of the book without annotation, thus losing much of its value. The index is excellent, but the tyro in thyroid disease would soon lose himself in the maze. A research worker in thyroid disease would find this volume interesting if only because of the author's wide and long experience.

Health Education of the Public: A Practical Manual of Technic. By W. W. Bauer, B.S., M.D., Director, Bureau of Health and Public Instruction, American Medical Association, and Thomas G. Hull, Ph.D., Director, Scientific Exhibit, American Medical Association. Cloth. Price, \$2.50. Pp. 227, with 39 illustrations. Philadelphia & London: W. B. Saunders Company, 1937.

This practical manual of technic of health education of the public sets forth in detail the various means of health education at the disposal of the health officer, the medical society or the individual physician. It shows clear understanding of these methods and, while it explains them simply, they are discussed thoroughly. The authors first point out some of the sources of material for the health educator: books, magazines, health agencies, federal and local, and medical colleges and universities, with various lists of agencies where information can be obtained. The authors then evaluate the various means of disseminating this health information: the radio, the exhibit, the meeting, pamphlets, the newspaper, the motion picture, stereopticon slides, the magazine article, correspondence, books and miscellaneous devices, such as the healthmobile. They discuss each of these methods to determine how each of them can be used most effectively and they also give a list of subjects that may be used for timely talks. Every health educator should have a copy of this manual at hand for reference purposes.

Approved Laboratory Technic: Clinical, Pathological, Bacteriological, Mycological, Parasitological, Serological, Biochemical and Histological. By John A. Kolmer, M.D., Dr.P.H., Sc.D., Professor of Medicine, Temple University, Philadelphia, and Fred Boerner, V.M.D., Assistant Professor of Bacteriology, School of Medicine and Graduate School of Medicine, University of Pennsylvania, Philadelphia. Second edition. Cloth. Price, \$8. Pp. 893, with 392 illustrations. New York & London: D. Appleton-Century Company, 1938.

As the title indicates, this edition was prepared under the auspices of the American Society of Clinical Pathologists. Each chapter has been revised and five new chapters have been added. These cover the subjects which have assumed importance in the seven years since publication of the first edition. Special emphasis is given to parasitology. The chapter on tissues also includes directions for the preparation of museum specimens. The most reliable methods and only those tests of approved value are given. The text is clear and concise; the procedures are definite and leave nothing to the imagination. Clinical pathologists, medical technicians and physicians performing laboratory tests will find this book not only a valuable one to own but the most reliable one to consult.

A Survey of Chronic Rheumatic Diseases Contributed by Contemporary Authorities in Commemoration of the Bicentenary of the Royal National Hospital for Rheumatic Diseases, Bath, 1738-1938. Compiled under the direction of the following Editorial Committee: R. G. Gordon, M.D., D.Sc., F.R.C.P., Chairman, G. P. R. Aldred-Brown, M.A., D.M., J. Barnes Burt, M.D., F. J. Poynton, M.D., F.R.C.P., R. Waterhouse, M.D., F.R.C.P., and G. D. Kersley, M.D., M.R.C.P., Secretary. Cloth. Price, \$6.50. Pp. 338, with illustrations. New York, Toronto & London: Oxford University Press, 1938.

This volume is issued to commemorate the bicentenary of the founding of the Royal Mineral Water Hospital at Bath. Its aim is to survey the current knowledge of rheumatic diseases. In pursuit of this purpose, recognized students of rheumatism from many lands have contributed chapters on different aspects of these diseases. Following a brief foreword reviewing some of the history of the Royal Mineral Water Hospital and its contributions to the country, especially in time of war, the book opens with a scholarly chapter on the history of chronic rheumatism by Sir Humphry Rolleston. While of necessity the discussion touches only the high spots, it serves as an excellent introduction to the subject. The French "concept of 'arthritisme'" is contributed in a chapter by Bezançon and Weil; a chapter on the osteo-arthritic syndrome by Polak of Paris is included. Professor Kahlmeter of Stockholm contributes an excellent chapter on the sedimentation rate in arthritis,

and Lindstedt of the same city on the pathogenesis and etiology of sciatica. The United States is ably represented in the excellent chapter by Hench on whether rheumatoid (atrophic) arthritis is a disease of microbic origin, one on the pathology of nonspecific arthritis by Ghormley, and chapters by Pemberton and Scull and by Osgood. Freund of Vienna has a chapter on the importance of biochemistry in the investigation of rheumatic diseases, and Aschoff of Freiburg on allergy in arthritis. Although most of the other chapters are, of course, written by eminent Englishmen, Van Dam of Amsterdam has one on radiography in rheumatism and the volume closes with one on organization and treatment of chronic rheumatism by Professor Van Breemen of Amsterdam. In spite of the multiplicity of authorship, the book is more than a collection of essays. It constitutes in its entirety a broad gage discussion of the present state of knowledge in many aspects of rheumatic diseases. No one, beginner or specialist, could fail to read it without obtaining much that is both informative and thought provoking.

Life and a Living: Report of the Committee for the Care of the Jewish Tuberculous, 1913-1936. Paper. Pp. 65, with illustrations. New York, [n. d.]

This report of the Committee for the Care of the Jewish Tuberculous deals with the care and rehabilitation of the tuberculous patient after graduation from the sanatorium. Through the Altro workshops, operated by the committee, the convalescent tuberculous person is given opportunity for paid employment. Easy jobs, light work or part time jobs are not always to be found. Employers still hesitate to place the ex-tuberculous among their apparently healthy employees for fear of infection. Hence the ex-tuberculous person finds it doubly hard to become self supporting. The aim of the Altro workshop as described in this report is to restore as far as possible the worker to his place in the community. This is not the only object of the rehabilitation program by this committee, as the committee points out that by its program it reduces materially the relapses among the patients discharged from the sanatorium. This booklet will be of value to the physician who has an interest in the problem of the ex-tuberculous in industry. Mention is made of similar projects in England, but no word is found of other like endeavors in this country.

Effect of Chronic Vitamin E Deficiency on the Nervous System and the Skeletal Musculature in Adult Rats: A Neurotropic Factor in Wheat Germ Oil. By Lårus Einarson, M.D., Professor of Anatomy, and Director of the Institute of Anatomy, University of Aarhus, Denmark, and Axel Ringsted, M.D., Assistant at the University Institute of Hygiene and the State Vitamin Laboratory, Copenhagen. Translated from Danish by Hans Andersen, M.D. Paper. Pp. 163, with 97 illustrations. Copenhagen: Levin & Munksgaard; London: Oxford University Press, 1938.

The first part of this monograph describes the clinical manifestations of neuropathic disturbances that develop in adult rats on a diet without vitamin E. These disturbances are prevented under certain conditions by a factor in wheat germ oil. The second part is devoted to a careful description of the extensive anatomic changes that may develop in the nervous system and skeletal muscles of adult rats fed without vitamin E. Whether the neurotropic principle in wheat germ oil is identical with vitamin E is not fully decided, but the facts at hand indicate that the two are identical.

The Chemistry of Antigens and Antibodies. By J. R. Marrack. Medical Research Council, Special Report Series, No. 230. Paper. Price, 3s. Pp. 194, with 27 illustrations. London: His Majesty's Stationery Office, 1938.

This report is a revised edition of report 194, published in 1935 under the same title. The usefulness of the earlier report indicated the need of revision in order to include the many important results of the work during the last few years on the chemistry of antigens and antibodies. The first chapter discusses such fundamental matters as the shapes and sizes of molecules, intermolecular (polar) forces, the structure of proteins and the stability of suspensions with special reference to antigen-antibody reactions. Then comes a consideration of the nature of antibodies, mainly from the point of view of their relation to proteins. The special topics considered are the

separation of antibodies from other serum constituents, the stability of antibodies, the antigen-antibody complex, the relation of antibody globulin to normal globulin, and the increase of serum proteins on immunization. The third chapter deals with the specificity of antigens, including artificial and natural protein antigens, polysaccharides and lipins. The last two chapters take up the nature of the antigen-antibody reaction, which is divided into two stages, specific combination and secondary reaction. At the end of each chapter is a list of appropriate references. There is a complete index. The first edition contained 135 pages. A work of great interest and usefulness to all students of pathogenic organisms and immunology has been brought well and thoroughly abreast of the times.

Actinomycosis. By Zachary Cope, B.A., M.D., M.S., Surgeon to St. Mary's Hospital, Paddington. Cloth. Price, \$5.50. Pp. 248, with 60 illustrations. New York, London & Toronto: Oxford University Press, 1938.

According to the author, this is the first monograph on actinomycosis in English. The first six chapters deal with general aspects of the disease: definition and history, characteristics of actinomyces, incidence, clinical features, diagnosis, prognosis and treatment. The history of the infection, the characteristics of the organism, the incidence, the general clinical features, the diagnosis, prognosis and treatment of the disease are considered as well as its localizations in different organs and tissues. There is a selected bibliography, an index of names and a subject index. Most of the illustrations are borrowed from older publications and many are now mainly of historical interest. Eight are in color. The monograph summarizes conveniently the knowledge of actinomycosis but it does not say anything about the disease that has not been said before.

Maternal Care Complications: The Principles of Management of Some Serious Complications Arising During the Antepartum, Intrapartum, and Postpartum Periods. Approved by the American Committee on Maternal Welfare, Inc. Prepared by R. D. Mussey, M.D., P. F. Williams, M.D., and F. H. Falls, M.D., F. L. Adair, M.D., Editor. Cloth. Price, \$1. Pp. 95. Chicago, Illinois: University of Chicago Press, 1938.

This booklet was written because of the enthusiastic response to the monograph which was published last year by the American Committee on Maternal Welfare, Inc., under the title "Maternal Care." The second volume presents the essential facts concerning the three major causes of maternal mortality, namely the toxemias of pregnancy, hemorrhages and puerperal infection. The three chapters were prepared by R. D. Mussey, P. F. Williams and F. H. Falls respectively. The second volume, like the first, should be carefully read and reread by every physician who practices obstetrics. If the general practitioners of this country were to learn the principles enumerated in this book and apply them to the best of their ability, there would be considerably less cause for worry about maternal and fetal death rates which exist at present. Every physician who cares for obstetric patients should possess a copy of this book.

An Introduction to Clinical Scotometry. By John N. Evans, M.D., F.A.C.S., Professor of Clinical Ophthalmology, Long Island College of Medicine. Published for Long Island College of Medicine. Cloth. Price, \$4. Pp. 266, with 57 illustrations. New Haven: Yale University Press, London: Oxford University Press, 1938.

This scientific monograph represents a compilation of study and material that the author has accumulated during the past nine years and is an effort to bring together the evidence from various sources so that it may be more available than in its present widely disseminated form in the periodical literature. In the fourteen main chapters he traces the history of plotting the central field of vision from the early part of the seventeenth century down to the present highly technical method of angioscotometry that he has developed and perfected. The necessary equipment, the technic, the application to clinical conditions and the theoretical considerations involved in central field work are described in sufficient but not unnecessary detail. There are enough illustrations to emphasize the desired points. The by-paths of angioscotometry are considered in the various appendices and to round it out there is a working bibliography of 320 references. As the name of Evans is intimately associated with angioscotometry, it must be stated emphatically that the book

is not given over to the highly scientific but clinically impractical plotting of the retinal vessels but deals rather with the clinical scotomas of the central visual field. Consequently the volume should have a definite place in the library of every modern ophthalmic clinician.

Structural Variations of the Human Iris and Their Heredity With Special Reference to the Frontal Boundary Layer. By Viggo Eskelund, M.D. Paper. Price, 21s. Pp. 243, with illustrations. Copenhagen: Nyt Nordisk Forlag, Arnold Busck; London: H. K. Lewis & Co., Ltd., 1938.

This monograph deals with the structural variations of the iris and to a lesser extent the cornea. The author endeavors to classify the variations in his own inimitable manner, with a view to establishing the limit of the structural variations, their mutual relation and their frequency. The photographic examinations of the anterior surface of the iris were carried out on hundreds of patients and the endeavor was made to trace a hereditary relationship in the contour of the various aspects of the anterior iris. This was successful in only a limited percentage, corresponding to the earlier investigation of Weninger. Forty-four iris photographs, enlargements of Graflex prints, are reproduced. In the majority of instances the individual iris markings are badly blurred and this is increased by corneal reflex of the photo-flash lamp that was used for illumination. The photographs could not be called an unmitigated success. The last eighty-four pages of the monograph are devoted to an analysis of the patients, numbering well over 160. With each case is given the Bertillon-like formula of structure of the iris. However, the endeavor to classify human beings by the forms of the iris, similar to the classification by the form of the finger prints, is not a success. Neither is the relationship of iris structure sufficiently accurate to permit of recognition of paternity. The monograph is closed with a short bibliography. The enormous amount of work represented by this book must be available to interested research workers in libraries, but it is not worth a place in the library of a practical ophthalmologist.

The Pharmacological Shock Treatment of Schizophrenia. By Dr. Manfred Sakel. With a foreword by Professor Otto Pözl, Chief of the University Clinic for Neurology and Psychiatry of Vienna, Austria. Authorized translation by Joseph Wurtis, M.D., Research Fellow at the Bellevue Psychiatric Hospital of New York. Enlarged version of a series of articles from the Wiener medizinische Wochenschrift, 1934-35. Nervous and Mental Disease Monograph Series No. 62. Cloth. Price, \$2.15. Pp. 136, with illustrations. New York & Washington: Nervous and Mental Disease Publishing Company, 1938.

The book presents in convenient form Sakel's method of the insulin treatment of schizophrenia. The procedure is clearly outlined and many suggestions are made which will be helpful to the practitioner. Emphasis is laid on individualizing the procedure in different cases, but the criteria which decide at what phase the treatment should be interrupted are vague. A number of case histories are critically discussed. Sakel undoubtedly deserves credit for showing that schizophrenia can be "cured" by a treatment involving definite physiologic changes in the brain, but his attempts to account for them are unscientific. It seems to be regrettable that a book that is bound to be read by psychiatrists all over the country contains passages such as "The action of insulin therefore consists in: (1) neutralization of the excitant hormone and (2) vagotonic muffling of the cell." Investigations of other authors on the insulin treatment are almost completely omitted.

Surgical Handbook for Hospital Assistants in the Tropics. By W. K. Connell, M.B., Ch.B., F.R.C.S., Surgical Specialist, Tanganyika Territory. Cloth. Price, 12s. 6d. Pp. 440, with 177 illustrations. London: John Bale Medical Publications, 1938.

The problems presented in this book have no interest for medical practitioners in general. Army medical officers, especially in the tropics, might find this small volume instructive in the training of the orderly. The problems presented are peculiar to the British tropical service with its experience with native dispensers. Because of the quasimedical nature of its audience, presentation is dogmatic and brief. This is a dangerous policy, since duties seem to extend beyond first aid into the realm of diagnosis and treatment, which always require competent medical care.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Damages: Paralysis Following Cerebral Hemorrhage Mistaken for Drunkenness.—The plaintiff, a minister of the gospel, was a passenger on a bus operated by the Tri-State Transit Company. When the bus arrived at its destination the driver observed that the minister remained in his seat, apparently asleep, and attempted to arouse him. He was unable to do so and, thinking that the man was drunk, he called a helper and the two lifted the minister bodily from the seat in the bus, carried him into the waiting room of the station, put him in a chair, and left him. A short time thereafter, an outsider went into the waiting room and saw the minister lying prostrate on the floor. The ticket agent for the transit company, on being informed by this outsider of the supposed drunken condition of the minister, telephoned police headquarters stating that there was a drunken man at the station lying on the floor and asked that some one be sent to take charge of him. Two policemen who came in response to the call assumed, too, that the minister was drunk, carried him to police headquarters, entered a charge of drunkenness against him and locked him up. Apparently no further attention was paid to him until about twenty-four hours later, when the city physician was notified and immediately discovered that the minister had suffered a cerebral hemorrhage which had almost completely paralyzed him and rendered him speechless. A brother of the minister, summoned from a distance of about 100 miles, came and took charge of him. While at the time of the trial the minister's condition had considerably improved, he was still paralyzed and totally incapacitated. He brought suit against the Tri-State Transit Company and the Interurban Transportation Company for damages. The trial court's judgment for the defendants was affirmed by the court of appeals and the plaintiff appealed to the Supreme Court of Louisiana.

The Interurban Transportation Company was absolved from liability because the evidence showed that it had no contractual relationship with the plaintiff, who intended to continue his journey over that bus line but had purchased no ticket. The Supreme Court was of the opinion that the plaintiff had failed to make out his case against the remaining defendant, so far as he claimed damages for permanent and total disability. According to the testimony of physicians, it was not at all likely that medical attention, if administered immediately after the plaintiff suffered the stroke, would have averted the paralysis. In their opinion the paralysis which totally disabled the plaintiff would in any event have followed the stroke.

The assumption of the employees of the bus company that the plaintiff's limp and helpless condition was due to drunkenness, said the court, was extremely far fetched. But assuming that they did so believe and that they acted in good faith, their mistake was the misfortune of the company, and it is liable for injuries sustained by the plaintiff by reason of that mistake. After observing that a passenger is helpless and unable to take care of himself, from whatever cause, it is the duty of a carrier's employees to exercise reasonable care and diligence to make at least temporary provisions for his protection and comfort. A failure to do so is clearly a violation of the contract for safe passage. Instead of performing the duty in the present case, it was assumed without the slightest foundation, in the opinion of the court, that the plaintiff was in a drunken stupor and the report was spread abroad that he was drunk. Although the plaintiff was paralyzed and utterly helpless, he was not unconscious. He realized what was going on but could not explain or call for help. Not the slightest attention was paid to him during the time he lay in jail on the concrete floor. To say nothing of the pain and suffering resulting from the stroke, the suffering he must have undergone from the discomfort of lying on the floor without minis-

tration to his ordinary bodily needs, and the consciousness of his innocence and his utter inability to call for or to obtain help can well be imagined, the court said. He suffered some from the stroke itself. For this the carrier was not at fault. But the fact is that, if he had been afforded proper medical and other treatment, his discomfort and suffering would not have been so severe. For this item of damage, therefore, the court thought that the plaintiff should be awarded \$2,500.

As to the slander charge, there was no testimony that the plaintiff's reputation as a minister was injured. His friends and parishoners did not believe the report that he was drunk. But in the opinion of the court he was entitled to nominal damages for the false and slanderous charges made against him. The court assessed his damage under this item at \$1,000.

The judgments of the lower courts were therefore reversed and the Tri-State Transit Company was ordered to pay the plaintiff the sum of \$3,500.—*Scarcy v. Interurban Transp. Co., Inc., et al. (La.), 179 So. 75.*

Workmen's Compensation Acts: Traumatic Aggravation of Perthes' Disease.—The employee, in the course of his employment, slipped on a greasy floor and fell, with legs spread apart, on to his right hip and the lower part of his back. An examination by the company physician, made three days later, disclosed no swelling or discoloration of the parts of the hip and back where the employee complained of pain. Several days later the company physician again examined him and discovered a limitation of motion of his right leg. A roentgenogram revealed that the head of the femur in the right hip was flattened. The employee was paid compensation for a period of eight months, after which it was discontinued. Thereafter, he instituted proceedings to recover additional compensation. The industrial commission denied the application, finding that the employee was suffering from chronic Perthes' disease and that this, not the accident, was the cause of his disability. The employee appealed to the Supreme Court of Minnesota, predicated his right to recover additional compensation on the theory that the accident had aggravated the pre-existing Perthes' disease.

Perthes' disease, said the Supreme Court, has been recognized only within comparatively recent years. It has its genesis in childhood while the femur is in a formative state. Whether it results from infection or from trauma is disputed; but its effect, whatever the cause, is the flattening of the head and the broadening of the neck of the femur. Since the head of the femur thereby becomes maladjusted to the socket into which it is supposed to fit, some limitation of the normal movement of the leg necessarily results. After the initial flattening and broadening of the femur occurs, the condition may remain quiescent for many years, but during adult life it has been noted in some cases that chronic or degenerative arthritis later develops. In its more advanced state it is accompanied by pain, muscle spasm in the vicinity of the affected bone, and considerable limitation of movement of the leg. It may originate without the knowledge of the afflicted person; its resurgent activity after a period of quiescence has been said to be due to traumatism caused by the overuse of a mechanically imperfect joint. It was conceded by the employee that the flattened and broadened condition of the femur existed at the time of the accident. He was then 43 years of age and had been employed at heavy manual labor all his life. He had never been sick and could remember no accident which might have caused Perthes' disease during his youth. He claimed that this accident aggravated the condition of his femur and that since the accident he had suffered pain and muscle spasm in the area of his right hip, had been unable to stand on his feet for any considerable period, that the movement of his leg was limited and a limp had developed through the shortening of the right leg, and that there had been atrophy of the muscles of his right thigh. The physicians of his selection who examined and treated him following the accident substantiated his contention.

The medical witnesses called by the employer and those appointed by the industrial commission categorically denied the truth of the employee's assertions. They testified that the

roentgenograms taken soon after the accident, when compared with those taken two years later, failed to show the slightest change in the abnormal condition of the femur and that therefore there was no justification for an assumption that the condition of the femur differed in the slightest from its condition at the time of the fall. They maintained that the accident imposed a strain on the soft parts of the body on which the relator fell without affecting the femur, and that the period for which compensation was paid was ample to permit a recovery from those strains to the soft tissue. They admitted that the condition of the femur would impose some limitation on the movement of the leg, but contended that this limitation at the time of the trial was no more extensive than it was when the accident occurred.

The court could find in the evidence nothing to justify it in overruling the findings of the commission and the order disallowing compensation was affirmed.—*Henz v. Armour & Co. (Minn.)*, 277 N. W. 923.

Accident Insurance: Death from Botulism as Death from "Bacterial Infection."—A life insurance policy containing a double indemnity clause provided that double indemnity was not payable if the insured's death resulted "from the taking of poison or . . . from any bacterial infection other than bacterial infection occurring in consequence of accidental and external bodily injury." It was admitted that the insured's death was due to botulism contracted through eating home-canned beans. The insurance company denied liability for double indemnity, contending that the death was due to "the taking of poison" or to "bacterial infection." The trial court gave judgment for the beneficiary, and the company appealed to the Supreme Court of Colorado.

Webster's New International Dictionary, said the court, defines infection to mean the "process of infecting" and the word "infect" to mean "to contaminate with a disease-producing substance, germs or bacteria." Technically, the court continued, the illness produced by bacteria themselves is referred to as infection, while that occasioned by the poison produced by such bacteria is referred to as poisoning. Gould's Dictionary of Medicine defines "botulism" as poisoning and defines "infection" as "the communication of disease-germs or virus by any means, direct or indirect." The same authority defines disease as "a condition of the body marked by inharmonious action of one or more of the various organs owing to abnormal condition or structural change." All of this, the court pointed out, merely reinforces and confirms the popular interpretation or commonly accepted meaning of bacterial infection as covering such afflictions as botulism, admittedly caused by the germ known as *Bacillus botulinus*. In the amended complaint the beneficiary contended "That said deceased on April 21, 1937, ate home canned beans containing *Bacillus botulinus* and then and there became infected with said bacillus." This statement was repeated in the stipulation of facts. The contentions, therefore, of the insurance company that death resulted from "bacterial infection" seemed to the court to be admitted by the beneficiary. Hence the exception contained in the insurance policy covered the case and the double indemnity clause was not applicable. The court, therefore, reversed the judgment of the trial court and remanded the case with instruction to enter judgment for the insurance company.—*New York Life Ins. Co. v. Mariano (Colo.)*, 76 P. (2d) 417.

Evidence: Right of Physician Witness to Testify Concerning Probable Effect of Injury.—In the trial of a personal injury suit in which it was alleged that the plaintiff's left leg was fractured when he was struck by a car driven by the defendant, a physician called by the plaintiff was asked the cause of the pain from which the plaintiff testified he suffered. The physician stated that in his opinion it was caused by adhesions that tended to limit the function of the limb; that is, fibrous unions between two tissues resulting from inflammation. The physician was then asked whether in his opinion the conditions caused by the adhesions were likely to be permanent. Basing his answer on his observations of the tendons and the condition of the leg, on his own knowledge and on the history of the

patient, the physician stated that the conditions were likely to be permanent and that with reasonable certainty the pain would continue permanently in the future. Another physician, who had taken roentgenograms of the plaintiff, when asked his opinion as to the cause of the pain in the region of the fractures after any sustained use of the leg, attributed it "to the atrophy of the muscles, to the shortening of both legs, to the angulation of the fragments and the change in the weight bearing line," which was impaired by reason of the bowing and angulation of the lower left leg. All this testimony was admitted over the objection of the defendant. From a judgment for the plaintiff the defendant appealed to the Supreme Court of Michigan.

The defendant contended that the testimony of the physician witnesses outlined above invaded the province of the jury and was therefore inadmissible. The Supreme Court, however, took a different view. A physician, said the court, may testify as to the extent of certain injuries, whether the injury is permanent or not, the probability of recovery, and the probable results of the injury. This, the court thought, did not come within the rule that excludes the opinion of a witness as to the ultimate fact that the jury is called on to determine. A medical man may testify as to his opinions concerning the condition of the human system, the probability of recovery from an injury and other matters peculiarly within his professional knowledge. When the court or jury can make its own deductions, deductions may not be made by witnesses. In this case the probable effects of an injury such as that suffered by the plaintiff could be shown only by the opinion of a competent physician. The physicians testified fully as to the facts on which they based their conclusions and were entitled to give their opinions on the probable effect of the injury that the plaintiff received. For the reasons stated, and others not here pertinent, judgment in favor of the plaintiff was affirmed.—*Pearce v. Rodell (Mich.)*, 276 N. W. 883.

- Virginia, Medical Society of, Danville, Oct. 4-6. Miss Agnes V. Edwards, 1200 East Clay St., Richmond, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia

196:153-304 (Aug.) 1938

United States Army's War in the Air Against the Mosquito-Borne Diseases. J. S. Simmons, Boston.—p. 153.

*Statistical Study of Acute Hemorrhagic Pancreatitis (Hemorrhagic Necrosis of Pancreas). H. A. Weiner and R. Tennant, New Haven, Conn.—p. 167.

Acute Hemolytic Anemia. H. M. Greenwald, Brooklyn.—p. 179.

Observations on Etiology of Toxemias of Pregnancy: V. Etiologic Relationship Between Water Retention and Arterial Hypertension. M. B. Strauss, Boston.—p. 188.

Observations on Referred Pain of Cardiac Origin. S. Robertson and L. N. Katz, Chicago.—p. 199.

Paradoxical Embolism. D. W. Ingham, Rochester, Minn.—p. 201.

Radiologic Measurements of the Apical Basal Relaxation of the Lung During Artificial Pneumoperitoneum Treatment. A. L. Banyai, Wauwatosa, Wis.—p. 207.

Diabetic Coma Requiring an Unprecedented Amount of Insulin: Report of Case Manifesting Extreme Insulin Resistance. H. J. Wiener, New York.—p. 211.

Hyperinsulinism and Pregnancy: Report of Case. E. B. LeWinn, Philadelphia.—p. 217.

Uveoparotid Fever (Heerfordt's Syndrome): Neurologic Manifestations: Report of Two Cases. D. Arbuse and M. Madonick, New York.—p. 222.

Regeneration of Adrenal Gland Following Enucleation. D. J. Ingle and G. M. Higgins, Rochester, Minn.—p. 232.

Effects of Pressor Substance Obtained from Kidneys on the Renal Circulation of Rats and Dogs. A. Merrill, Atlanta, Ga.; R. H. Williams and T. R. Harrison, Nashville, Tenn.—p. 240.

Typhus Fever in Pennsylvania. H. F. Flippin, Philadelphia.—p. 246.

Disease and the Negro. G. Walsh and R. M. Pool, Fairfield, Ala.—p. 252.

Relationship of Orthopedic Surgery to Internal Medicine. H. T. Hyman, Long Branch, N. J.—p. 261.

*Effect of Prontosil and Related Compounds on Chemotropism of Leukocytes. D. R. Coman, Philadelphia.—p. 273.

Acute Hemorrhagic Pancreatitis.—The belief that alcohol is in some way related to acute hemorrhagic pancreatitis has developed in the department of pathology of the New Haven Hospital from a review of the clinical histories of fatal cases of this disease. This has been fortified by a not infrequent case with an explosive clinical course and striking postmortem observations, in the light of which Weiner and Tennant undertook an analysis of 4,000 necropsies. Each anatomic diagnosis was reviewed and all protocols in any way related to pancreatic disease were abstracted, with especial emphasis on the clinical history (including alcoholism), the chief anatomic causes of death and also the postmortem condition of the stomach, pancreas, liver and gallbladder. All the available slides of liver and pancreas in these cases were reviewed. There were thirty-eight instances of acute hemorrhagic pancreatitis and ninety-seven of chronic pancreatitis. In twenty-five of the acute cases, alcohol was an associated factor. In six, disease of the extrahepatic biliary tract was present. Of fifty-one persons dying during acute alcoholic episodes, twenty-seven had pancreatic lesions (twenty-five acute and two chronic). In forty-one instances of chronic alcoholism nineteen showed pancreatic lesions, all of a chronic nature. In fifty-one instances of periportal cirrhosis, twenty-five showed pancreatic lesions. In 343 cases of disease of the extrahepatic biliary tract there were six instances of acute pancreatitis and twenty-one of chronic pancreatitis. While the data offer no relation to the pathogenesis of acute pancreatitis, they indicate at least the complexity of the problem. The results show an increase of from forty to fifty times in the incidence of pancreatic disease when a history of alcoholism exists.

Sulfanilamide Compounds and Chemotropism of Leukocytes.—Coman conducted experiments using a sulfanilamide compound (Prontosil-Losung, Bayer) absorbed on kaolin, carbon and streptococci in an attempt to determine the chemotropic effect of the drug for polymorphonuclear leukocytes. Leukocytes were obtained from the peritoneal cavity of rabbits. Although the prontosil slightly reduced the negatively chemotropic effect of kaolin, it did not cause a positive chemotropic response. Adsorbed to carbon and to streptococci, the prontosil did not alter the directional movement of the leukocytes in relation to the adsorbing agents. There is, then, no evidence from these experiments that prontosil attracts leukocytes. Experiments in which sulfanilamide (Merck) was used as the attracting substance showed that this substance exerted a toxic effect on the leukocytes which was expressed in a cessation of their movements. Experiments in which a benzoyl derivative of sulfanilamide (setazine, Merck) was used as the source of attraction showed that this substance exerted only a weak attraction for the leukocytes and this was not constant. It seems unlikely from these experiments that the therapeutic action of these drugs is due to an increased chemotropism of polymorphonuclear leukocytes.

*Oral Ragweed Pollen Therapy: Clinical Results of Experiments on Gastrointestinal Absorption. T. B. Bernstein and S. M. Feinberg, Chicago.—p. 297.

Infectious Diseases: Review of Current Literature. H. A. Reimann, Philadelphia.—p. 305.

Culture of Human Marrow.—Osgood found by studying cultures of human marrow that sulfanilamide exhibits a slight bacteriostatic action on pneumococcal infections which is increased by an increase in concentration. Even 0.3 unit per cubic centimeter of specific antipneumococcus serum is more effective against the type I pneumococcus than is sulfanilamide alone. Sulfanilamide plus any given dose of antiserum less than the amount which will by itself reduce colony counts to nearly zero is more effective than corresponding doses of antiserum alone. The results support the view that sulfanilamide renders the organism more vulnerable to bactericidal substances present in the serum: If the results of these in vitro experiments are applicable to infections in human beings, sulfanilamide therapy should be of value in pneumococcal pneumonia and might delay death in pneumococcal meningitis, but alone it will not prove as effective as even small amounts of type-specific antiserum. If used in conjunction with antiserum it should further lower the mortality with the present doses of antiserum or should give an equally low mortality with smaller doses of antiserum.

Experimental Streptococcal Endocarditis.—Kinsella and Muether injured the mitral valve or the chordae tendineae of seventeen dogs and then fed them living cultures of non-

hemolytic streptococci either mixed with food or by stomach tube. Ten of the animals became sick, displayed positive results of blood culture and died. At necropsy these infected animals had bacterial endocarditis. The bacteria in the vegetations were found to be identical with those that had been fed to the animals. Bacteria entering the animal body through the mouth may become implanted on an injured area within the body. The exact route which these bacteria follow is not determined.

Oral Ragweed Pollen Therapy.—Bernstein and Feinberg gave extract of ragweed pollen to twenty patients allergic to ragweed. The duration of treatment was from one to three weeks. In determining the strength of the initial doses the relation of the oral to the hypodermic dose was kept in mind. One drop of a 1:33 extract of ragweed pollen was regarded as a probably safe initial dose, since it is about 450 times the strength of the first dose (0.05 cc. of a 1:10,000 extract) usually given hypodermically. The doses were given three times daily well diluted. In most instances the maximal dose was from 10 to 15 drops at the end of a week. In two cases a maximal dose of 30 drops was used. No benefit whatever was experienced by eighteen patients with regard to the symptoms of hay fever and asthma. Two obtained moderate improvement, in one of whom while there was some improvement in the hay fever there was no improvement in the asthma. In other words, there was no amelioration of the asthma in any instance. In six patients the pollen extract caused gastrointestinal disturbances, consisting mainly of colicky addominal pain and nausea.

Cerebral Changes in Psychosis.—Elvidge and Reed obtained twenty-six specimens of cerebral tissue for biopsy from nineteen psychotic patients between 20 and 40 years of age; thirteen with schizophrenia, five with manic-depressive psychosis and one with so-called toxic encephalitis. A second operation was performed on seven of the patients at the end of from one to two years, and thus useful data were furnished as a control. Sixteen specimens serving as controls were taken from routine surgical material with a similar or an identical technic. Swelling of the oligodendroglia cells occurred in association with schizophrenia and manic-depressive psychosis. There was often accompanying mild hypertrophy of the astrocytes. Two main types of oligodendroglial change were observed: that in which the nuclei were normal and that in which they were pyknotic. Swelling of oligodendroglia cells was observed in two patients with status epilepticus who were mentally confused between seizures. It existed in one patient at the time of an epileptic seizure. The change in the oligodendroglia cells in psychotic patients occurred in the white matter. It may be general or patchy in distribution. At a depth of 1 cm. and in the deeper layers it was often more intense. In view of the changes in the oligodendroglia cells, it is suggested that the mental phenomena are associated with massive physiologic disturbances in associational and commissural fibrous pathways in the brain. In this way impulses from different parts of the brain are interrupted, with consequent disturbance and loss of control in the intellectual, volitional and

emotional fields. By analogy with the other states in which swelling of oligodendroglia cells is observed, it is justifiable to assume that in psychotic states also there may be a causal toxic or metabolic factor.

After-Contraction.—How far one may utilize the concept of after-contraction in studies of ordinary motor learning Sapirstein and his collaborators do not say, but for the production of after-contraction a large initial stimulus produced by external forces is not necessary. Supporting the weight of the limb itself is sufficient. In walking or running there is a repetitive movement, perfectly coordinated, which eventually is made with almost no conscious effort; indeed, the movement seems entirely automatic. It is easily believable that a basic factor involved here is that represented by after-contraction, which is a sustained cortical excitatory state responding in a rhythmic fashion to stimuli of which the subject is unconscious. Physiologically, after-contraction is influenced by facilitation, fatigue and changes in initial load and duration of effort. The phenomenon is always reinforced by simultaneous contraction of ipsilateral muscles and is frequently inhibited by contraction of contralateral muscles. A relatively normal reaction is associated with tabes and cerebellar syndromes, a prolonged after-contraction with paralysis agitans and a diminished response with disease of the pyramidal tracts. After-contraction is mainly an after-discharge from the cortex or its projection pathways. It is modified by other parts of the nervous system, as is voluntary activity. Suggestions are offered concerning the usefulness of after-contraction as a method of investigating the physiologic behavior of the cortex and of studying drugs used in controlling its excitability. Theoretical views are advanced as to the possible role of after-contraction in habit formation.

Staphylococcal Conjunctivitis.—In view of the efficacy of immunization with staphylococcus toxin in protecting rabbits against instillations of toxin which would produce severe conjunctivitis in normal rabbits, Thygeson attempted to obtain healing in fifty-seven human beings with conjunctivitis by immunization with toxoid. Only persons were chosen whose conjunctivitis had resisted local treatment for not less than two months. The majority of the patients had had conjunctivitis for more than a year. The toxoid was given biweekly, starting with an initial injection of 0.01 cc. of dilution. 2. The dose was increased to a maximum of 1 cc. in steps of 0.02, 0.04, 0.06, 0.08, 0.1, 0.2, 0.4, 0.6 and 0.8 cc. Injections of less than 0.5 cc. were given intradermally and the remainder were given subcutaneously. In cases in which noticeable improvement did not occur on completion of the series, injections of 0.5 cc. were continued at weekly intervals for at least six weeks. Healing occurred in twenty-one of the fifty-seven patients, nineteen showed clinical improvement and the condition of seventeen remained unchanged. The cultures of twenty-four of the fifty-seven patients became negative. There was a recurrence of symptoms after periods varying from four to six months in eight of the persons in whom clinical healing occurred. In all these the symptoms disappeared after a second course of toxoid therapy. This recurrence was probably related to the fact that in seven of the eight patients

some toxigenic staphylococci were still present after healing. The cultures of the thirteen patients in whom healing occurred, and who have as yet had no recurrence, were negative after healing. The results obtained warrant further clinical trial of staphylococcus toxoid.

Delayed Resolution in Bronchopneumonia.—In considering the problem of delayed resolution in bronchopneumonia it seems likely to Cole that one is not dealing with a true pathologic entity but with a variety of conditions. There is a definite need for more clinical investigation under controlled conditions. Many cases of this nature are seen in the home in which facilities for careful diagnostic studies are lacking. Under ideal conditions, one should have serial roentgenograms in every case of bronchopneumonia. Bronchoscopic examination should be made of those patients who fail to recover promptly. It may be found that so-called nonresolution is really due to localized areas of atelectasis or to occlusion of a bronchus or a bronchiole. Treatment is bound to be empiric until the condition is better understood.

Extrapleural Pneumothorax in Pulmonary Tuberculosis.—Up to the present Overholt and Tubbs selected only those patients for extrapleural pneumothorax for whom any other form of collapse therapy offered no hope of a successful outcome. Extrapleural pneumothorax is not introduced to replace the modern selective thoracoplasty but is an alternative measure when the latter is contraindicated. The factors which render the patient with pulmonary tuberculosis unsuitable for thoracoplasty are evidence of too great activity, extensive bilateral lesions of a fibrocavernous nature and complicating factors (insufficient cardiovascular reserve, generalized emphysema, asthma and the like). The operation has been performed thirty-one times (in twenty-eight patients) under cyclopropane and oxygen inhalation anesthesia or a combination of local infiltration with paravertebral block of the upper intercostal nerves, 1 per cent procaine hydrochloride being used. On return to the ward, an oxygen tent has rarely been needed even in the bad risk patients. Intravenous infusion has been used if the blood pressure fell below 100 systolic, so that the patient may

sit up soon after operation. All the patients had more or less interstitial emphysema during the first twenty-four hours, but in no case has it caused any distress other than slight tenderness of the affected tissues. Sputum was not retained for more than thirty-six hours. Following pneumolysis, patients are able to expectorate more efficiently and sooner than after thoracoplasty. The frequency and amount of air refills to maintain the space so as to give the desired selective collapse have been controlled by frequent roentgenograms, fluoroscopy and consideration of the manometric pressures. In three cases almost the whole space became filled with blood clots which could not be aspirated through a needle. Infection in the extrapleural space developed in four patients. In three of these there is definite evidence of a bronchial fistula. In another case evidence is lacking, although it is possible that the lateral wall of the cavity became necrotic because of its separation from the wall of the chest. Regardless of this complication, the patient has improved sufficiently to consider thoracoplasty. The authors believe that most of the patients will eventually require conversion of the extrapleural pneumothorax to the permanent collapse of thoracoplasty. This prediction is made because of the extensive disease present in those selected for this form of treatment. Should the operation eventually be applied more widely to include young patients with less extensive disease, the ultimate fate of the space would be subject to the same rules that apply to an intrapleural pneumothorax.

Pain Following Operations for Sinus Disease.—Skillern presents the variable theories on the persistence of sinus pain after operations on the sinus as expressed by sixteen leading rhinologists. A tabulation of the opinions gives the following causes in order of frequency for the persistence of pain: incomplete operation, disease elsewhere than in the sinus operated on, systemic disease causing symptoms of sinusitis, synechiae or scar tissue blocking drainage or enmeshing the nerve, direct injury to or interference with a nerve, operation on the ethmoids and turbinates for insufficient reason, individual nervous reaction to pain, neuritis of the fifth cranial nerve, atypical neuralgia of unknown origin, reaction to insult of the periosteum and bone, injury to the sympathetic plexus and diversion of normal air currents within the nose. As long as there is any evidence of sinus infection the obligations of the otolaryngologist have not been fulfilled, and the persistence of apparent sinus pain means further study in conjunction with specialists in other fields of medicine until they have found the cause and, if possible, relief has been obtained. The author believes that the persistence of pain (1) in the frontal sinus after radical operation may be due to failure to remove every

vestige of infected material, localized meningitis or osteomyelitis, abscess in the frontal lobe and/or infection in another sinus; (2) in the maxillary sinus to injury to the infra-orbital foramen, injury to the dental or infra-orbital nerve, reinfection from overlying sinuses, failure to remove all the infective material from the sinus and infection of an adjacent cell (anterior ethmoid) causing symptoms resembling those of maxillary sinusitis, and (3) in the ethmoid capsule and sphenoid sinus traumatized periosteum or bone near the foramen, direct injury to the nerves or blood vessels, proximity of the meninges (localized meningitis or osteomyelitis) and failure to open the long, narrow, fronto-ethmoid cell, the thin slitlike orbital or any anatomically misplaced ethmoid cell that may be infected. The ethmoid capsule and the sphenoid are considered as one, as synechiae may follow an operation, with the walling off of isolated areas of infection.

Tuberculous Peritonitis.—Since the favorable results of operation in tuberculous peritonitis are out of proportion to the amount of surgical work performed, there must be some other explanation of why these patients improve. It seems likely to Brown that in some cases equivalent improvement may be accomplished by the use of closed ether anesthesia alone. A temporary anoxemia produced by the anesthesia might be an explanation for the apparent cures. The tubercle bacilli are known to be aerobic organisms. From the known facts of culturing the tubercle bacilli, the reduced oxygen intake of the body would explain, at least partially, the improvement that follows when ether anesthesia alone is administered. The chemical study of the tubercle bacillus shows that such compounds as lipoids, fatty acids, acetone-soluble fat and wax can be isolated. Since the blood carries a large volume of ether vapor during anesthesia, it is possible that some chemical reaction may take place with one or more of these substances to cause permanent injury to the organisms or to produce an oxygen impermeable membrane about them. Such speculations on a chemical basis would tend to uphold further the proposed theory of anoxemia as an explanation of improvement in cases of tuberculous peritonitis following closed ether anesthesia alone or accompanying a surgical procedure. A study of cases of tuberculous peritonitis in which operation has been performed with spinal anesthesia would do much to settle the question of whether inhalation anesthesia is a factor in the improvement.

Exercise and Metabolism.—Mills studied the metabolism of two subjects who were not in athletic training before and after a walk of ten miles in the postabsorptive state. One subject, the author, who lived habitually on a high carbohydrate diet, showed an inconstant lowering of the respiratory quotient after the walk, but no ketonuria or depression of tolerance to dextrose, even when he restricted the carbohydrate in his diet. The other subject, who habitually consumed a lower proportion of carbohydrate, always showed a low respiratory quotient and ketosis after a walk unless he greatly increased the intake of carbohydrate in his diet. His tolerance to dextrose was considerably depressed after the walk, but if he had been living on a high carbohydrate diet this depression was absent. Curves of blood sugar have been plotted for the second subject after intravenous injection of insulin. Those after exercise did not differ from those before in the phase of falling blood sugar, showing that the depressed tolerance to dextrose was not due to a reduced sensitivity to insulin. After exercise there was, however, a delay in the return of the blood sugar to normal and determinations of respiratory exchange after injection of insulin suggested that at this time this may have been due to a higher level of carbohydrate metabolism. Insulin was found to raise the respiratory quotient much further after exercise than before.

Precision in Spinal Anesthesia.—Lake outlines a technic for precise spinal anesthesia in the carrying out of which the patient, who may have had a preliminary injection of morphine and atropine, is given an injection of 1 grain (0.065 Gm.) of ephedrine and is then placed face downward on the operating table. Pillows are now packed under the lower part of the chest to produce a well marked dorsal curve. The back is marked with iodine to indicate the intercristal plane, the second and third lumbar interval and the seventh dorsal spinous

process. The dorsal curve is now "sighted" against a horizontal black line painted on the wall of the operating room, and the table is tilted until the marked seventh spinous process lies at the apex of the curve. The head is kept flexed well down so that no solution can reach the cervical region. By means of the same solution with a hypodermic needle a wheal is raised on the skin at the point of injection and a little of the solution is also placed along the proposed needle track. A fine-bore stainless steel needle is now introduced at this level in a direction exactly vertical to the surface in all planes. The passage of the needle should be deliberate and slow so that the penetration of the dura can be easily felt. The needle is rotated and pushed on slightly to determine that the aperture is well within the dura and it is then turned so that the lateral aperture points up the spine. A syringe is attached to the needle, care being taken that the latter suffers no displacement. The solution, 1:1,500 nupercaine in saline solution, warmed to body temperature, is injected slowly to avoid turbulence and, as far as possible, to get the nupercaine solution to travel as a "bundle" to the highest point of the theca. At least two or three minutes should be taken to introduce from 6 to 9 cc. of the solution. The quantity to be injected varies a little with the size of the patient and the nature and expected duration of the operation. When the injection is completed the needle and syringe are held steady for a further thirty seconds and then withdrawn. The patient now remains in the same posture without movement for ten minutes and is then turned on his back, the pillows being removed and the table tilted into the head-down position. The operation may be immediately started. The author has now used this technic for nearly three years in many hundreds of cases and has obtained uniformly good results. It requires no complicated apparatus beyond the ordinary tilting operating table. Severe headaches are rare and there have been no other neurologic sequelae.

Hemolytic Streptococcus and Rheumatism.—Goldie states that there is clinical, immunologic and pathologic evidence of an etiologic relationship between rheumatic fever and rheumatoid arthritis. Immunologic data are presented to show that infection with the hemolytic streptococcus is more prevalent in these two diseases than in normal persons. Myocardial changes showing some resemblance to those characteristic of rheumatic fever have been produced in animals sensitized to bacterial protein, and this lends support to the theory that rheumatic fever and rheumatoid arthritis result from sensitization to the hemolytic streptococcus.

Sedimentation Rate and Anemia.—Hynes and Whitby constructed "sedimentation curves" according to the method of Wintrobe and Landsberg (1935). From observations of thirty-eight normal students a normal curve was constructed and the limits of the normal sedimentation rate were confirmed. Curves were made from forty-six cases with abnormal sedimentation rates. Curves were also made from eleven anemic patients whose blood, when reconstructed and rendered nonanemic by the addition of corpuscles, had normal sedimentation rates. These curves, whatever the degree of anemia, were precisely of the type obtained from normal students with similar sedimentation rates. In the same way the degree of anemia was found not to influence the shape of the curves for cases with abnormal sedimentation rates of the same order. These facts confirm the principle of correcting the sedimentation rate for anemia in terms of the hematocrit reading according to the method of Wintrobe and Landsberg.

Survival and Cure in Dementia Paralytica.—Vervaeck points out that the majority of about 2,000 publications that have appeared since the beginning of the era of malaria therapy of dementia paralytica is concerned with the clinical and social results of this treatment. Reviewing the figures given by different investigators about the percentages of remissions obtained with this treatment, the author found that they differ widely. He investigated the condition of patients with dementia paralytica ten years after they had been treated at a psychiatric clinic in Brussels. Investigations were made on the men who had been treated during the years 1926 and 1927. Dementia paralytica being less frequent in women, the follow-up studies were extended to the female patients who received treatment during the four years from 1925 to 1928 inclusive. Of fifty male patients, forty-one had been subjected to malaria therapy; and of fifty-three women, forty-two had been so treated. Of the forty-one male patients who had been treated with malaria, seven were still outside an asylum ten years after, but one of these died two months later, aged 53; four others had died outside an asylum, one of them after a second sojourn there; one lives in an asylum, again demented after having been at liberty for two years; seven died in an asylum where they had been returned; seven live in an asylum which they were never able to leave; thirteen died in the asylum, never having left it; two disappeared, and one of these was probably cured. Evaluating these results, the author concludes that in 64 per cent of the men with dementia paralytica who had been subjected to malaria therapy the results were unfavorable. After citing the later fate of the forty-two women with dementia paralytica who had received malaria therapy, the author shows that among these the frankly unfavorable results likewise amounted to 64 per cent.

- Effect of Fluid Diet and of Blood Loss on Development of Typhoid. L. Ambard, P. Barthelme and P. Mandel.—p. 1209.
 *Acetarson Therapy of Dementia Paralytica. L. Marchand.—p. 1211.

Acetarson Therapy of Dementia Paralytica.—Marchand's report is based on the results obtained with acetarson in the treatment of 111 patients with dementia paralytica. None of the patients treated were, or had been, subjected to malaria therapy. Three times a week the patients were given a subcutaneous injection of 1 Gm. of sodium acetarson dissolved in 10 cc. of distilled water. The total for a series of treatments was 45 Gm. The series were separated by intervals of three or four weeks. In the first two injections only half of the dose, that is 0.5 Gm., was given, in order to test the sensitivity of the patient. During the first few weeks of treatment the patients were kept in bed. The number of series of treatments required varies in different patients. Some of the patients are able to leave the hospital after the first series. In some of the patients, in whom the dementia paralytica advanced rapidly, the author intercalated between the acetarson injections an injection of quinine bismuth iodide until a gingival border appeared. Tests for syphilis were made on the blood and on the cerebrospinal fluid, before as well as after the treatment. The temperature was measured every day and the weight was determined before the treatment and then every month. An examination of the fundus oculi was made before the treatment and every two weeks thereafter. The author lists the results of the treatment in a tabular report. He says that he obtained "social recuperation" in seventy-one (64 per cent) of the 111 patients and improvement in ten patients (9 per cent); fifteen patients (13.5 per cent) died. The author speaks of "social recuperation" in those patients in whom the mental defects have disappeared so that they are able to resume their former occu-

pations but who are not cured organically. The social recuperation was obtained in twenty-six patients after one series of treatments, in twenty-six after two series, in eleven after three series, in six after four series and in two after five series. Following a discussion of the behavior of the reactions in the blood and in the cerebrospinal fluid in the patients in whom social recuperation was obtained, the author discusses the relapses. He says that nine of these patients had to be hospitalized again, because of the recurrence of mental disturbances. The relapses are due to a premature arrest of the treatment, to an insufficiency of the doses or to excessive length of the intervals between the series of injections. The patients with dementia paralytica who have been treated with acetarson should be kept under clinical and serologic control for several years after the treatment. The complications that may appear in the treatment with acetarson are slight in comparison to the severity of the disease. Discussing the contraindications to treatment with acetarson, the author says that the treatment should be avoided in senile subjects who present organic difficulties. However, tabetic symptoms and alcoholism without hepatic insufficiency do not constitute contraindications to treatment with acetarson.

 *Hepatic Opothrapy and Cholesteremia: Experimental Study. P. Van de Calseyde.—p. 712.

Hepatic Opothrapy and Cholesteremia.—Van de Calseyde reports experimental studies on the effect of liver therapy on cholesteremia. Studies were made on human subjects as well as on animals. It was found that it is not possible to determine the antianemic power of liver preparations on the basis of the variations in the cholesteremia which they engender in normal human subjects and animals. There is no parallelism between the variations in the cholesterol content and the antianemic power of the extracts. Nevertheless the author thinks that his observations on the hypercholesteremia produced by the ingestion of whole fresh liver or of certain liver extracts used for the treatment of pernicious anemia is of considerable biologic interest. His investigations proved that the increase in cholesterol is not due to the factor that exerts the therapeutic action in pernicious anemia, to the cholesterol content of the liver or to the vitamin A content of the liver. The appearance of the increase in cholesterol after ingestion of hydrosoluble extracts prepared according to the methods of Cohn and Gänsslen seemingly indicates that the agent inducing hypercholesteremia is neither a lipid nor a protein. Further investigations will be necessary to determine the chemical nature of the hypercholesterolizing factor of the liver. Other questions that await answers are: Is this substance present in tissues other than those of the liver? Is it related to the vitamins or hormones? By what mechanism does it increase the cholesterol content?

Metabolism After Injections of Horse Serum.—Conti observed the behavior of nitrogen and chlorides in the blood and of urea, uric acid and the chlorides in the urine of twelve normal persons who were given intramuscular injections of from 20 to 50 cc. of normal horse serum. The injections were administered at intervals of twelve hours until 140 cc. had been given. In all cases the injection was followed by increased azotemia, increased elimination of urea, uric acid and the chlorides in the urine and lowering of the chlorides in the blood. According to the author the results show that the proteins in the serum are disintegrated and eliminated shortly after the injection in a

similar manner to that which takes place in plasma proteins after transfusion. The results confirm the author's opinion that the plasma has a mechanical action on the blood, that the plasma proteins are disintegrated and eliminated shortly after transfusion and that disintegration of the erythrocytes takes place several days after transfusion with consequent liberation of erythrocytic proteins which are used by the blood. Assimilation of erythrocytic proteins reestablishes the equilibrium of the blood.

*Galvanocautery Puncture in Suppurative, Acute Lymphadenitis of Neck in Infants. G. Cigada.—p. 113.

Galvanocautery Puncture in Lymphadenitis in Infants.

—Cigada reports satisfactory results from puncture by means of the galvanocautery in twenty-seven cases of either acute abscess or acute suppurated lymphadenitis of the neck. Both the therapeutic and the cosmetic results are satisfactory. The tiny scars left by the puncture are almost invisible and they disappear in a few months. Puncture by the galvanocautery has no contraindications. It is done without anesthesia. The perforations remain open all through the process of elimination of pus. It gives more rapid results than many of the other treatments commonly resorted to in these conditions. As a rule it suffices for complete elimination of the pus. The best results are obtained when the pus is in a circumscribed cavity or when the different cavities of an abscess are punctured and also when the pus is already near the superficial layers of the tissues. It is advisable to use galvanocautery needles of medium size in order to make well opened outlets for rapid and sufficient elimination of pus. Local hot applications and complementary treatments (vaccines) are indicated. The total number of perforations is from three to five. Only in rare cases is reopening of the perforations or a surgical incision necessary. The treatment is well tolerated by infants and children.

Epinephrine Treatment of Malaria. V. Romeo.—p. 1562.

Action of Thymus on Blood Formation.—De Candia and Floriani observed the behavior of the blood and of the spleen in twenty normal persons with normal sized spleen after an intramuscular injection of 2 cc. of thymus extract which contained 1 Gm. of fresh gland for each cubic centimeter of the extract. The observations were made during fasting. Determinations of the changes of the blood and of the spleen were made half an hour and one hour after the injection. The erythrocytes and the leukocytes, but principally the former, increased during the first hour. The leukocytic formula gave different results in various persons of the group. There was an increase of the monocytes and parallel diminution of the neutrophilic polynucleated leukocytes in some cases, moderate increase of either the lymphocytes or the neutrophilic polynucleated leukocytes in other cases and the leukocytic formula did not change at all in still other cases. In all cases the size of the spleen diminished during the first hour following the injection (3 cm. in the longitudinal diameter and 2 cm. in the transverse diameter) and the diminution lasted for more than an hour. In two groups of patients (the number of which is not specified by the author) suffering from either fibrous forms of splenomegaly (Laënnec liver cirrhosis, Banti's disease and bantiform syndromes) or malarial splenomegaly, they found that the size of the spleen did not change or had a slight change in fibrous forms of splenomegaly, whereas the injection induced a more or less energetic contraction of the spleen, which lasted for more than an hour in the group of patients who were suffering from malarial splenomegaly. The authors believe that the intramuscular injection of thymus extract can be used for the differential diagnosis between fibrous and malarial forms of splenomegaly. It can be used also instead of epinephrine in the treatment of malarial splenomegaly by means of repeated induced contraction of the spleen.

Intra-Uterine Administration of Estrogen.—Grumbrecht

and Loeser say that experimental studies on the pathology and therapy of ovarian insufficiency revealed that the requirements for the action of estrogen on the various organs differ considerably. For instance, whereas the castration atrophy of the sex organs can be counteracted by the parenteral administration of estrogen, the changes which castration produces in the thyroid can be counteracted only if the substance is administered by way of the uterus. If it is administered by any other than the uterine route, it exerts no influence on the thyroid. The authors studied the reaction of the uterus to the local application of various estrogenic substances. They made experiments on infantile rats and guinea pigs and on mature rats. They found that the intra-uterine application of different estrogenic substances produces proliferation of the uterine mucosa with smaller doses and in a much shorter time than is the case in subcutaneous administration. The observations in the course of the animal experiments suggested to the authors the possibility of the clinicotherapeutic utilization of the intra-uterine administration of estrogen. For use in human subjects they employed suppositories which were from 4 to 5 cm. in length and a few millimeters in thickness. Each suppository contained 500 international units of estrogenic substance in a base of theobroma oil. The suppositories were sterile and were stored on ice. The authors say that their introduction into the internal uterine os was not difficult. In order to prevent the slipping back, a strip of gauze was introduced into the cervical canal for three or four hours. With this mode of application, undesirable complications such as increase in temperature, pains or local irritations were avoided. The case histories reported by the authors indicate that the intra-uterine administration of estrogenic substance is effective in cases of hypomenorrhea and secondary amenorrhea and in uterine hypoplasia with ovarian insufficiency and oligomenorrhea.

Lumbosacral Neuritis.—Pette and Becker

show that lumbosacral neuritis is a definite disease entity. On the basis of nine selected cases, they demonstrate the different forms the disease may take as regards the symptomatology and the course. The subjective and objective symptoms indicate that the morphologic changes, although as yet they have not been verified by anatomic studies, are chiefly in the region of the sympathetic centers and tracts. The clinical aspects, together with the somewhat characteristic changes in the cerebrospinal fluid, suggest that the disorder is an inflammatory process of spinal ganglions in the region of the lumbosacral plexus. Accordingly the authors designate it as a neuritis of the lumbosacral plexus. The disorder is closely connected with herpes zoster, they say, and consequently it can be classified with the group of virus diseases of the nervous system. The as yet hypothetical causal agent is characterized by neurotropic properties. As in other virus diseases of the nervous system (poliomyelitis, rabies), the term neurotropism is applicable in its restricted sense in lumbosacral neuritis. From the fact that a predisposition to so-called

rheumatic disorders and to excessive sympathetic reactions is frequently observed not only in the patients themselves but also in members of their families, the authors conclude that constitutional factors play a part in the pathogenesis of lumbosacral neuritis.

Neurology and Neurosurgery of Angina Pectoris. H. Jessen.—p. 1149.

Types of Diphtheria Bacilli and Course of Diphtheria.

—Werner says that among 134 cases of diphtheria in which the type of bacillus was determined there were eighty-four cases with the type gravis, forty-two cases with the type intermedius and eight cases with the type mitis. A relationship between the course of the disease and the type of the diphtheria bacillus could not be detected. There was no evidence that one type of bacillus would cause a severe form of diphtheria and another type a mild form. A change in the type of bacilli was observed in 9.7 per cent of the children; in all others the same type of bacillus was detected throughout the entire course of the disease. It was not possible to furnish definite proof of a real change in type. Since the available space did not permit a segregation of the patients according to the type of bacillus, there was always a possibility of superinfection with another type of bacillus. The persistence of positive smear tests was considerably longer in the patients in whom the gravis type of bacillus was present than in the patients with the intermedius type.

Inhalation of Hydrogen Sulfide Gas.—Hellfors reports the history of a man aged 63 who had angina pectoris after he had inhaled hydrogen sulfide gases while he was conducting experiments. In response to treatment the attacks of angina pectoris subsided somewhat but they recurred after renewed exertion. Then the patient contracted influenza, in the course of which the angina pectoris was aggravated. He died in a severe attack of angina pectoris. On the basis of this case history, the author suggests that the angina pectoris-like pains which are observed in persons with similar intoxications are due to temporary circulatory disturbances in the coronary vessels. He admits that two brothers of this patient likewise had angina pectoris, but he nevertheless thinks that the hydrogen sulfide intoxication was the eliciting factor of the angina pectoris in the reported case, because fourteen months previously the patient had a slightly increased blood pressure but no signs of coronary disease.

Anterior and Posterior Rachischisis. A. J. P. Van Den Broek and S. Van Dam.—p. 3666.

Blood Group and Diameter of Erythrocytes.—Tjiook Kiem Bok was induced to investigate a possible relationship between the blood group and the mean diameter of erythrocytes by a report of Pijper, who in studies on forty-eight cases was believed to have found evidence of such a relationship. Tjiook Kiem Bok made his tests on 500 healthy persons (students, nurses and laboratory staff). He determined the four classic blood groups and the mean diameter of the erythrocytes, respectively, by the method of Moss, Lee and Vincent and the diffraction method, using Pijper's blood cell tester. From this investigation the following conclusions could be drawn: 1. A correlation between blood group and red cell diameter, as Pijper assumed, could not be demonstrated. 2. The mean diameter of the erythrocytes of these persons is 7.3 microns, with a normal range of from 6.8 to 7.9 microns. 3. Sex has no influence on the mean diameter.

Simplified Method for Diagnosis of Pregnancy According to Kapeller. Adler. N. Nielsen.—p. 1144.

Boeck's Iritis.—Østerberg describes the case of a girl, aged 14, in whom a torpid, indolent monocular nodulous iritis developed and in the course of a year reduced the vision to 2/50 and threatened perforation of the eye. Enucleation was contemplated. There were no pulmonary symptoms but the roentgenogram of the lungs resembled a miliary tuberculosis and operation was deferred. In the course of nine months spontaneous recovery of the eye occurred, with restoration of vision and of the exterior of the eye almost to normal, and spontaneous regression of the pulmonary changes. Microscopic examination of tissue from an apparently healthy tonsil demonstrated sarcoid of Boeck. The author asserts that there is a distinct Boeck's iritis which is not identical with iritis tuberculosa; it is less painful, less destructive and more proliferative than iritis tuberculosa. The differential diagnosis must be based on the patient's general condition and the tuberculin, roentgen and microscopic examinations. Iritis is a relatively rare symptom in Boeck's disease, occurring in from about 5 to 10 per cent. Twenty-seven cases of Boeck's disease with iritis are tabulated from the literature.

*Heerfordt's Syndrome (Uveoparotid Fever), Manifestation of Boeck's Sarcoid. M. Jersild.—p. 765.

Solitary Nonparasitic Hepatic Cysts.—Baumgarten says that about 100 cases of solitary nonparasitic hepatic cysts have been reported in the literature since 1864. The majority of the cysts are caused by retention in the bile ducts, due to congenital malformation or to local obstruction of small intra-hepatic bile ducts. Most of them give no symptoms. If symptoms do occur, they are usually due to pressure on neighboring organs. Exact diagnosis is rarely made before operation or necropsy. The only effective therapy is surgical intervention, and the ideal operation is extirpation. The highest operative mortality occurs in cases in which puncture is done, the lowest in radical operations. In the case reported, in a woman aged 26, extirpation of the cyst was followed by recovery.

Heerfordt's Syndrome.—In Jersild's two cases of Heerfordt's syndrome the roentgenologic changes in the lungs led to the diagnosis of sarcoid of Boeck. In spite of the extensive processes the patients felt remarkably well and the Mantoux reaction, as frequently described in cases of sarcoid of Boeck and Heerfordt's syndrome, was positive only on larger doses of tuberculin. In one case with exanthem, biopsy supported the diagnosis. The author suggests that, since the etiology of sarcoid of Boeck is not clear, the relation of the disease to uveoparotid fever, which generally appears as an infectious disease with acute onset, may open new perspectives. Heerfordt's syndrome, he says, is surely the initial stage in a long-continued chronic infectious disease.

100: 777-806 (July 14) 1938

*Investigations on Etiology of Epidemic Hepatitis. T. T. Andersen.—p. 777.

Etiology of Epidemic Hepatitis.—Andersen asserts that jaundice in swine, contrary to the common conception, is a parenchymatous liver disorder corresponding to hepatitis in man and is transmissible to other swine and other animals, which demonstrates the infectious nature of the disorder. His investigations also show that hepatitis in swine probably originates from a similar latent infection in rats. Since there is hepatitis in swine and since, according to statistical studies, an alimentary infection is probable in man, he is inclined to believe that hepatitis in swine is one of the causes of hepatitis in man and is in Denmark presumably the most important cause.

THE STUDENT SECTION

of the

Journal of the American Medical Association

Devoted to the Educational Interests and Welfare of Medical Students, Interns and Residents in Hospitals

SATURDAY, OCTOBER 1, 1938

Obstetric Education

EDWIN F. DAILY, M.D.

CHICAGO

The practice of medicine in America has been the subject of discussion, praise and criticism during the past few years perhaps to a greater extent than during any previous comparable period of time. At no time in our history have American physicians been so aware of the interest of the people in the quality and quantity of medical services available.

The interest always manifested in the illness and death of mothers and infants has resulted in numerous studies of the underlying factors causing the maternal and infant mortality in different parts of the United States. The results of these studies made by medical specialists in their respective fields have been constantly brought to the attention of both the medical profession and the public.

The White House Conference in 1930 studied all phases of the problem and published many volumes which are valuable sources of factual information. Following the exhaustive study of maternal mortality in fifteen states made by the Children's Bureau, maternal-mortality surveys were made in many states and in many of the larger cities in the United States. The results and conclusions of all these studies are remarkably alike. Analyses have been made of all factors concerned in maternal mortality, and the responsibility assigned to the physician has not been small. The fact that lack of judgment or negligence on the part of the physician is responsible for a portion of the maternal deaths in the United States has caused not a little concern but has resulted in few constructive programs for improving the situation. In the last generation there has been considerable improvement in the care received by maternity patients in this country, but this improvement has not kept pace with that of most of the other medical specialties.

The art of obstetrics has been considered strictly as a part of medical practice in the United States and without doubt it will con-

tinue to become increasingly so in the future. No one who is familiar with the high professional standards of the medical profession in the United States doubts that the average physician practicing obstetrics renders service to the best of his ability and knowledge. Since the quality of obstetric care received by a patient depends primarily on the amount and type of education and experience her physician has had in this specialty, we are concerned primarily with a consideration of these subjects. There can be no doubt that if every physician practicing obstetrics had a thorough basic knowledge of antepartum care and of the conduct of labor there would be fewer tragedies of childbirth.

The Council on Medical Education and Hospitals of the American Medical Association reported in 1937 that "the teaching of obstetrics is at a lower level than that of the other major clinical departments. Comparatively few schools offer to their students an adequate practical experience under competent supervision. This may result from a variety of causes, one of which is, undoubtedly, the failure of administrative authorities to provide access to a sufficient amount of clinical material. Another may be the feeling on the part of teachers that the practice of obstetrics should be reserved for specialists and that therefore the ordinary undergraduate does not need much training along this line."

Eight years ago the White House Conference Committee on Obstetric Teaching and Education stated that:

The better the clinical training of students in the art of obstetrics, the better obstetrics they will practice, and this in turn will be reflected in improved results. . . . The need is not for less theory but more clinical instruction. . . . In so far as obstetrics is concerned, the majority of students at the time of graduation are not qualified to assume the responsibilities of caring for maternity cases. . . . They may have had in most instances sufficient theoretical training but they lack actual experience. It is obvious, then, that obstetric educational facilities in this country have been entirely inadequate in so far as the teaching of actual delivery care is concerned. There have been and still are too few well organized women's

Instructor, Department of Obstetrics and Gynecology, University of Chicago; Director, Maternal and Child Health Division, U. S. Children's Bureau.

clinics in connection with medical schools to give the necessary training and experience to medical students, to say nothing of the dearth of facilities for developing specialists in this field.

Few medical schools today have sufficient clinical obstetric material available for the instruction and training of their students in antepartum, delivery and postpartum care. The importance of such instruction and training is illustrated by the fact that in a Midwestern state, according to a recent survey, more than 50 per cent of the physicians include obstetrics in their practice.

Dr. W. C. Danforth, chairman of the Illinois Committee on Maternal Welfare, wrote in 1936:

The ideal remedy for the high maternal mortality in this country would be to provide obstetric attendance and well equipped hospitals in which women in labor may be cared for. This ideal state of affairs will not arrive for a long time but gestation and labor will continue.

Some attempt must be made to improve the present conditions while we wait for the changes which time will no doubt bring. For many years, in any event, most of the women in the majority of our states will continue to be cared for by general practitioners. It is not fair to demand of the man in family practice the same familiarity with and skill in the handling of all the obstetric problems which are sometimes presented. He must also meet medical problems in many other fields, and the incessant demands upon his time, if he is a successful practitioner, make a minute knowledge of any special field impossible. In many communities, in our own state as in others, the general practitioner may be compelled to meet situations which would tax the skill of the specialist in his fully equipped hospital, assisted by a trained personnel. Without special knowledge, lacking trained assistance and the material resources of a hospital equipped to deal with obstetric emergencies, he cannot be too greatly criticized if, in some cases, his results are not ideal. He must, however, have sound fundamental knowledge of obstetrics and realize not only what it is wise to do but also what it is unsafe to attempt.

Before considering what changes might be desirable in obstetric education, let us review a few facts concerning the education now provided.

A recent Children's Bureau questionnaire answered by 2,538 graduates of sixty-one medical schools in 1936 revealed that with regard to the study of obstetrics:

Lectures were begun by 44 per cent in the second year.

Lectures were begun by 55 per cent in the third year.

Clinical training was begun by 4 per cent in the second year.

Clinical training was begun by 70 per cent in the third year.

Clinical training was begun by 25 per cent in the fourth year.

Practically 100 per cent reported that their clinical training included examination and care of women during pregnancy, labor and the postpartum period. This survey shows that didactic and clinical obstetric teaching begins during the second or third year in most medical schools; it does not, of course, reveal the amount

of instruction given or the knowledge of the instructors of the principles of obstetrics as applied to actual practice. As Dr. Weiskotten pointed out in his survey of medical schools: "It would appear that in many instances far too little attention has been given to the selection of the faculty. It is safe to assume that a teacher should have some special preparation and that an individual who has had no such training or experience in a subject is not competent to teach it." The failure of some schools to teach students how to practice obstetrics in the best interests of their patients under the conditions they must work under in homes and in small hospitals is responsible in no small part for their difficulties in later practice.

STUDENTS' CLINICAL EXPERIENCE

Concerning their clinical experience while in medical school, the 2,538 recent graduates reported the facts presented in table 1.

The "Essentials of an Acceptable Medical School," approved by the House of Delegates of the American Medical Association, states that every medical student should have actual charge of fifteen maternity patients under the supervision of a clinical instructor, yet 19 per cent of these students delivered no patients in hospitals and 27 per cent had no home deliveries as part of their training. Fifty-nine per cent of the students had a total of twenty or fewer deliveries in hospitals and homes. Twenty-three per cent of the students reported delivering ten or fewer patients in hospitals and homes.

The number of patients a student delivers is in itself no indication of the clinical training received, for without competent instruction and supervision the experience is of little value. However, with so few actual deliveries by students it is obvious that the amount of experience and instruction must be extremely limited for a large proportion of the students.

According to the "Essentials of a Hospital Approved for Training Interns," prepared by the Council on Medical Education and Hospitals of the American Medical Association in 1935, an intern should deliver at least ten patients while in the service. Concerning their obstetric experience during internship, the recent graduates referred to reported the facts given in table 2.

Twenty-two per cent reported delivering ten or fewer patients in home and hospital during their internship.

Thirty-two per cent reported delivering twenty or fewer patients in home and hospital during their internship.

Of the interns who attended hospital deliveries, 22 per cent reported that their deliveries were not supervised by an obstetrician.

Seventy-two per cent of these graduates plan to include obstetrics in their practice and 15 per cent plan to specialize in obstetrics. Eighteen

per cent of them did not believe that their obstetric training in medical school and during internship qualified them to include obstetrics in their practice. Sixty-three per cent of them wished to receive more obstetric training, and 23 per cent reported that they were unable to do so because of too few hospital appointments in this field.

There are only eighty-eight approved hospitals in the United States admitting more than a thousand patients annually which offer residencies in obstetrics or obstetrics and gynecol-

TABLE 1.—Deliveries by Medical Students

| Number of deliveries..... | 0 | 1-10 | 11-20 | More Than 20 |
|---|----|------|-------|--------------|
| Percentage of students delivering this number in hospitals..... | 19 | 49 | 17 | 15 |
| Percentage of students delivering this number in homes..... | 27 | 43 | 22 | 8 |

ogy. Only forty-three of this number offer both resident and assistant resident positions. In these hospitals there are only about 150 resident or assistant resident appointments in obstetrics and obstetrics and gynecology made each year.

One inescapable conclusion of this questionnaire study of obstetric education is that the average physician entering practice today does not have sufficient clinical training in obstetrics to recognize and treat competently the many complications that may arise during pregnancy and labor. The importance of this conclusion is emphasized by the limited number of specialists in obstetrics, most of whom are concentrated in a few large cities.

GRADUATE STUDY

Attempts to provide postgraduate lecture courses in obstetrics for local practicing physicians have accomplished little more than to make the individual physician realize more than ever his inability to provide competent obstetric care. There has been a great demand from these physicians for opportunities to return to clinical teaching centers for further training. Most of them have been disappointed, for there are few places where they may go for such training. Opportunities for practicing physicians to return to the larger teaching hospitals have been provided to a certain extent in several states and an increase in the number of these may be expected in the near future.

The problem confronting certain medical schools is the difficulty in making sufficient clinical obstetric material available for all the students. This lack of teaching material cannot be remedied easily, if at all, in many medical schools.

The establishment of a few maternity centers primarily for teaching purposes in selected areas, especially in the South, would provide opportunities for additional clinical training for

many students and practicing physicians. These maternity centers should provide care for the medically indigent patient and afford opportunities for research, and should be supported by public funds. The greatest difficulty in establishing such centers would be encountered in staffing them with instructors who are willing and competent to teach sound, conservative, routine obstetrics rather than to demonstrate their surgical skill or unusual cases of great interest to them but of little practical teaching value.

In order to provide competent medical care for a larger proportion of maternity patients, either there must be greater opportunity for obstetric training before graduation and during internship, or the practice of obstetrics must gradually be limited to those men who have had opportunities for special training in obstetrics subsequent to their ordinary internship. Every effort should be made to increase the number of resident appointments in hospitals with maternity services and to secure the services of the best obstetricians in the community to teach and supervise the work of the interns and residents.

Whatever progress in obstetric education is to occur in the near future will depend to a great extent on the study and careful consideration by every one concerned in the teaching of obstetrics of (1) the instruction and training now given medical students and graduates and (2) the results of the services these physicians render their patients when in practice.

The importance of adequate instruction for undergraduate and graduate students has been recognized and stressed by teachers of obstet-

TABLE 2.—Deliveries by Interns

| Number of patients delivered..... | 0 | 1-10 | 11-20 | More Than 20 |
|---|----|------|-------|--------------|
| Percentage delivering this number in homes during internship | 82 | 13 | 2 | 3 |
| Percentage delivering this number in hospitals during internship..... | 15 | 9 | 10 | 66 |

rics for many years. Unfortunately the tremendous social importance of such instruction is not recognized by teachers in other medical fields and by the administrators of medical schools who listen to but do not act effectively in carrying out programs of obstetric education advocated by teachers of obstetrics.

If obstetrics is to maintain its position as a recognized medical specialty in the United States, our physicians must receive sufficient undergraduate and graduate training to enable them to guide their patients safely through pregnancy, to conduct deliveries with the skill and judgment required, and to recognize the value of expert consultation when complications arise.

Comments and Reviews

THE ART AND TECHNIC OF STUDY

Thousands of students are at present returning to medical schools throughout the United States to continue their studies or to engage in the study of medicine for the first time. Each one of the various medical curriculums will require of the students great concentration of effort and continuity of attention. In this long process the students naturally will acquire habits of study, and it seems desirable for them to be guided by certain general principles which may increase their efficiency and make more effective the hours of study. Such is the intention of the following opinions of some writers who have given special attention to the technic of study.

Walker¹ points out that medical students are far too ready to slump into a condition of subnormal physical health. A reaction tends to set in early against the athletic activity of the public schools when undergraduate life is reached, but sound physical health must be maintained. The rich opportunities given by university life for the preservation of physical fitness should be exploited fully. A certain proportion of each week and each year should be set aside exclusively for recreation. Of equal importance is the development of mental stamina, which term includes not only the acquisition and maintenance of will and judgment, remote alike from rashness and pusillanimity, nor merely the ability to sacrifice the present to the future, but also the cultivation of the gentler arts of the world. Medicine may be a jealous mistress, but he who gives her his all will never experience the contentment and philosophical security which a broad general culture imparts. During the student years, time must be found for the study of a science for its own sake—any subject which appeals to the individual—or for the cultivation of literature or an art. The necessity for travel in the student years must be mentioned. During these tours, either at home or abroad, there can be no harm in visiting the hospitals and schools; but any attempt at promiscuous study, Walker believes, should be suppressed.

In the study of medicine much knowledge has to be acquired in a relatively short time. While it is necessary to know, for example, that the islets of Langerhans are not in Polynesia, loading up with necessary facts is by no means the most important part of the curriculum. Much more important is the acquisition of technical

skill, dexterity, practical experience and clinical acumen. Of greater importance still is the keeping of a proper perspective during the various stages of the curriculum. In practical work and in reading, every student should examine his methods of study periodically, ruthlessly scrapping unprofitable habits and customs.

READING AND PRACTICAL WORK

Walker believes that reading should be done in the evening. The student should consider the technic of reading. At the outset, the student should decide whether he remembers best by merely looking at a written word, by writing it down or by hearing it spoken. That is, he should learn whether he has a "visual memory" or an "auditory memory." The former fortunately is more common. Every student must investigate his powers of memory by actual experiment, decide his own classification, and work on it. Once the most favorable channel for the reception of facts is decided, the details of study can be regulated. Study from books should be done in privacy in an environment conducive to alertness and clarity. Anything conducive to too much physical comfort must be shunned. No attempt should be made to read soon after a meal or when tired. Reading in the train or bus or "at any old time" is a waste of energy and promotes staleness. As a general rule, it is said that, if the practical work of a working day has been faithfully performed, two hours' book work in the evening is ample. It is then that reading should consolidate and fix the practical work done during the day.

Walker believes it should be an inviolable rule that whatever has been seen or heard in the lecture room, laboratories or wards during the day should have first claim on the time available for reading during the evening. Surgery must be read during the performance of surgical appointments, ophthalmology while the student is actually seeing ophthalmic patients, and so on. It is worse than useless to attempt to acquire the formal dogmas of medicine by suddenly beginning at page 1 in a large textbook. The greater part of each morning and afternoon should be devoted to practical work and training. The surpassing value of dissection, of study in the wards, outpatient department and receiving room, of lectures which flavor facts with a lecturer's personal experience, and particularly of the "writing up" of patients' records, needs no emphasis. It may be taken for granted that a "part" once thoroughly dissected is etched deeply in the memory. Similarly, a scientific or clinical investigation once thoroughly per-

1. Walker, G. F.: *The Technic of Study*, *Lancet* 2: 481 (Aug. 31) 1929.

formed repays the investigator many times over by conferring ineradicable knowledge. In dissecting, the student should display the region so that he can subsequently recall it in three dimensions. And in investigating patients, when once the full straight facts have been clearly displayed, the imagination should be invoked to illuminate the patient's own side of the problem. For the precise and formal extraction of data about a patient, there is no more pithy and significant advice than the exhortation "Look and see." The cultivation of sincerity and the preservation of an ever open mind should be comprised in that advice.

The technic of practical study needs as much watchful care as does the technic of reading. It is very easy during the clinical years to be in a place where work can be done, should be done, and is in fact being done—by others. The tendency to lapse into intellectual somnolence during demonstrations is insidious in its onset, but a habit of vigorous enthusiastic attention is not difficult to acquire and when once acquired is seldom lost. The mere acquisition of the habit is worth while for its own sake; its utility will probably outlive the utility of many of the topics to which it is first applied. A large teaching hospital usually abounds in places where dawdling is possible and prevalent.

Here are two little pieces of advice. First, the midday meal should be taken free from "shop." Secondly, the notebook is worth consideration—a good small loose-leaf notebook should accompany the student through his whole curriculum. It should be just small enough to fit in the pocket, it should be available at all times, and each night it should be tidied up and full pages withdrawn to be placed in appropriate accumulations.

THE COURSE AS A WHOLE

The really fundamental thing to grasp is that the course is a whole, and not a string of loosely connected segments each requiring a concentrated onslaught with subsequent relegation to the background. I do not mean, Walker says, that a student should attempt to go forward three steps at a time but that he should look on his curriculum as a series of phases of initiation into the science and art. Each phase prepares the student for subsequent phases but is very dependent for its full consummation on preceding phases. To reduce this to practical terms it may be said, for example, that anatomy and physiology should forthwith be continuously studied during clinical work.

It follows from the fact of the unity of the course that the textbooks of each phase should be retained and kept viable during subsequent phases. Revision and maintenance of knowl-

edge is safer and easier if done from the actual pages of the big textbook used during the phase when it was intensely studied. "I say big textbook, because one big textbook should be selected for each topic and adhered to from start to finish. The small summaries and cram books have their place, but they are mainly useful as a help to marshal facts. The author of a most successful synopsis, far from making the usual claim to be meeting a 'long-felt want,' says in his preface that ultimate reliance on anything but the larger books will lead to failure. Just as the textbooks of successive phases should be carefully retained throughout, so must the microscope not be sold. I do not mean that the shelves should be laden with large textbooks on the history of medicine, but the bald facts of study can be enlivened by reference to an encyclopedia when a proper name is found. And from time to time monographs should be perused."

EXAMINATIONS

It is useless to ignore the fact that examinations loom large in the curriculum. "I have many times told my student friends that the examination incidents—and I am convinced that 'incident' is the right word—should be happy episodes. This information has always evoked incredulity, but on several occasions graduates have subsequently admitted personal verification. Of course, only fools make light of examinations. They should be taken so seriously that the student, as soon as he enters a particular phase, should plan his work for the terminal examination of that phase by actual time-table and schedule. He should record diagrammatically his progress through the phase so that the work is spread evenly over the time available. As an example let us suppose that a phase of study in one of the ancillary subjects lasts six months and that the textbook concerned has 500 pages. Then 100 pages must be covered each month by schedule, the actual pages being selected each evening according to the nature of the particular lecture, demonstrations and practical work enjoyed during the day. The art of passing examinations consists in doing steady comprehensive work during the whole of the antecedent phase. He who works steadily in the practical work of a phase with concurrent systematic reading cannot be 'plowed.'"

BRIEF REST PERIODS

It may be practical to review the psychologic data whose interpretation may facilitate study, as has been done by Gillespie² at Guy's Hospital in London. It is found, he says, to be beneficial

2. Gillespie, R. D.: *The Art of Study: Its Principles and Their Application*, Brit. M. J. 2: 365 (Sept. 1) 1928.

if brief rest pauses are introduced at intervals during long periods of work. Thus not only may mental work be made more efficient but the output of factories has been favorably influenced. It is usually considered that to transfer one's attention to another task after feeling fatigued at a previous one is efficacious in restoring mental efficiency. The so-called "subjective fatigue," which is another name for boredom, tends to be abolished in this way. Mental fatigue is a matter of comparative unimportance. Only a small part of it is probably attributable to cerebral activity, and even this part is readily abolished by a rest pause or by normal periods of sleep. The greater part of mental fatigue is made up of boredom or by the so-called "specific objective fatigue," which is surmounted by changing over to another type of mental activity. The apparent mental incapacity in cases of "mental exhaustion" is nearly always the result not of intellectual effort but of anxiety or some other emotional disturbance, resulting from preoccupation with some personal problem. This is dramatically illustrated in the sudden recovery of persons complaining of "brain-fag" which has perhaps limited their work to periods of less than an hour each, when a source of worry is removed. Gillespie says that for practical purposes the mind is almost tireless. Even when there is considerable deprivation of sleep, intellectual work may be persistently maintained at a high level if the worker does not worry about his insomnia.

OUTSIDE INTERRUPTIONS

There is a factor called "warming up" that occurs as the task proceeds. Our mental machinery seems to have a degree of inertia which can be overcome only gradually. Hence the importance of avoidance of outside interruptions. To be called away to a telephone causes a greater loss in efficiency than is indicated by the mere loss of time; the amount of work done immediately after such an interruption is less than the output immediately before the interruption. It is desirable, therefore, to arrange work in such a way that it can be carried on without interruption for several hours at a time if need be. Much of the most difficult part of a difficult study is the beginning of it. A careful arrangement of very brief rest pauses will increase the total mental output, but the distribution and length of the pauses have to be worked out empirically by each individual for the type of work that he does.

Memory is one of the most important aspects of the mental process involved in study, but mere memory in the sense of physiologic retentiveness is not enough. To have it in a high

degree is an asset, but unless its stores are usable in an intellectual way a phenomenal memory may even be a hindrance. The author cites an experiment which seems to show that the last night's cram before an examination is of little benefit unless for the acquisition of entirely new material. We lose only slightly by abstaining from all work in the last few days before an examination and probably gain considerably in that elusive quality called "freshness."

In merely learning anything by heart, certain devices are of value. Grouping the material to be learned into intelligible unities naturally occurs to every one; presence of rhythm makes learning easier. It is easier to learn poetry than prose. It has also been found experimentally that, if a poem of several verses has to be memorized, it is more economical in the long run to learn it as a whole rather than stanza by stanza. We remember best what interests us most. Interest reduces also the effort both of attention and of remembering, and it increases the powers of observation as well. Interest leads also to selection and under its influence we select what we wish to remember often without realizing it.

But not everything, Gillespie says, should be left to this instinctive selection. With some people there is too much slavish routine reading, too much of plowing through masses of perhaps unnecessary and irrelevant textbooks, omitting nothing lest anything be missed, as some people read every page even of the inferior works of fiction produced by a good author.

MEMORIZING

There is no evidence for the statement, sometimes heard, that everything seen or heard or done is retained and that nothing is ever completely forgotten. Consider what would happen if we did not, practically at least, forget much of our experience. In recalling some event we would revive the smallest details and its recollection would require as much time perhaps as the event itself, and thus we would hardly have time available to register new impressions. Memory then is selective. The best memory is possessed by the man who makes the greatest number of associations with his experience; but the most effective memory is a combination of associative richness with selection. The man who thinks about his experience has much the better memory, and this marks the distinction between crammed information and real knowledge of the subject.

There are methods whereby association can be multiplied, and some of them are by discussion and debate and by reading different books in the same field, and also by writing

about the subject. Writers of textbooks and monographs frequently acknowledge that the persons to whom the writing has been most beneficial has been the authors themselves. It is not possible to write about every topic while preparing for an examination. A valuable exercise is the writing of papers; and they need not be necessarily on original work. It is good for the student to read regularly one of the current general medical periodicals, together with occasional issues of the more specialized journals. After graduation, the first few years often have to be spent by the young medical man in ridding himself of the unquestioning faith in authority and in the printed work that he has acquired during the student days, and of the parrot-like habits of memorizing rather than understanding.

The methods of study adopted must vary with the individual and with the nature of the subject. Some stress the regularity of habits of study, as a habit can thereby become established which has a certain dynamic effect of its own.

INCENTIVES TO STUDY

The subject "Incentives to Study" came to the attention of the Yale University student body a few years ago and found expression in a survey. A questionnaire was sent to each undergraduate and about 50 per cent of the total student body returned answers. Reviewing the summaries of this survey, Davis³ reaches the following conclusions: (1) Definiteness and direction of purpose become incentives to study; (2) concentration, rather than distribution, should be the curricular desideratum; (3) superior motivation placed Yale's poorer students in the lead in scholarship, but excessive financial handicap may overcome motivation; (4) it is the student's belief that for honor men the two final college years should be wholly tutorial; and these tutors should be the greatest teachers, instead of such men being reserved for the large lecture courses.

PROCESS OF STUDY

The following steps in studying any definite section of a subject are suggested by Ryerson of the University of Toronto: (1) collection of data, (2) selection and organization, (3) assimilation.

Data may be collected by the student from any source available. Selection and organization involve judging and condemning so-called facts, then dividing ideas into groups. Deductive reasoning descends from the general to the particular, while inductive reasoning separates the relevant from the unimportant. Safety and skill in neglecting some and accepting other

facts may be developed by proceeding from the principal thoughts to the details. The central idea must be found and firmly gripped. Principal thoughts must be searched for and recalled frequently for valuation. All articles should progress by groups of facts.

Assimilation is getting nutriment into usable form to accomplish a purpose. Ideas are recalled by their relation or connections with other ideas.

Individuality must be realized, the power to work must be developed, and system should be cultivated. Concentration of attention is to be acquired to eliminate waste.

MEDICAL PRACTICE OF THE FUTURE

What is it that leads men to enter the medical profession? In most cases the modest goal is that of earning an honorable living. Some cherish the ambition of contributing to the advancement of medical science, others the still loftier aim of serving their fellow men. An astute minority strives for personal aggrandizement and for the all too rare distinctions allotted to medical men. Whatever our initial impulse may have been, we have embarked on a swiftly flowing stream with many currents and hidden rocks. We should realize these hard facts. Considering all the circumstances of its past environment, the products of our orthodox system of education have been wonderfully good. Tradition is sometimes a valuable stimulus; on the other hand, it may act as a drag on imagination and progress. Under our present social and educational régime, an increasing proportion of bright young men and women throng our higher schools and universities, and in due course they swell the crowded ranks of the medical profession. Graduates are now turned out by mass production, more or less standardized and polished, like motor cars belonging to a particular factory and, like motor cars, tending to become out of date when compared with later models.

The young graduate, once he has secured his diploma of proficiency, usually has a transient wave of optimism. He soon discovers that he has fallen out of the frying pan of undergraduate life, even if supplemented by post-graduate experience, into the fire of everyday practice with new responsibilities and anxieties. He finds that the environment and equipment required for successful family practice are utterly different from the hospital conditions in which he has been trained. This is not strange, since few of his teachers have been through

3. Davis, James E.: Teaching and Learning, J. Michigan M. Soc. 35: 311 (May) 1936.

Abstract of an address delivered by Sir James Purves-Stewart before the University of Leeds Medical Society, Edinburgh M. J. 45: 309 (May) 1938.

the mill of general practice. The common diseases for which he is now consulted are unlike those dramatic clinical pictures on which he concentrated his attention in hospital wards and theaters. He comes to realize the truth of the aphorism that "there is no such thing as a disease; there is only a sick person," and that his success largely depends on studying and dealing with the personalities of his patients.

His primary problem is usually economic. A few lucky young graduates find comfortable practices awaiting them. The more brilliant students may be attracted to teaching or to research; others may undergo further training with the intention of qualifying as specialists. The majority are content if they can find congenial employment and economic independence. Even in England the supply of medical graduates is already becoming greater than the demand, although in this respect we compare favorably with some other countries. In Germany the proportion of medical men has become so high that the average graduate has to wait some ten years before he succeeds in attaining an independent practice. In France the proposal has recently been made that all medical men on attaining the age of 65 years should be compulsorily retired, they being treated as crumbling monuments. The economic problem is becoming increasingly anxious. And yet, after all, to the man of scientific mind, even when his own personal problem of earning a living is successfully solved, this is only the working foundation of his career.

Each generation of medical graduates differs from its predecessors. Until the middle of the nineteenth century, and later, every qualified practitioner was regarded as a completely equipped medical unit, a walking compendium of knowledge, able to attack any problem presented to him by his trustful patients. But since those days of the so-called all-round man, not only has the pace quickened but the load to be carried has become heavier.

The first stage of specialism in modern clinical work was when general or major medicine diverged from general or major surgery.

THE SPECIALTIES

The specialties within the medical profession are steadily increasing. The laboratory worker, the biochemist, the radiologist, the pharmacologist and others now perform work that is indispensable to the clinician, who has neither the special knowledge, the instrumental equipment nor the technical dexterity requisite for carrying out such observations. Secondly, there are the clinical specialists, who confine their activities to one special organ, or to one special

aperture of the body. Their field is sometimes so restricted that they frankly admit being incapable of dealing with ailments outside it. Imagine a modern ophthalmologist supervising an obstetric case or a dermatologist dealing with a compound fracture. And the gallant general practitioner is expected by the public to deal successfully with all such cases. Nevertheless we need the skilled ophthalmologist and the expert dermatologist.

Specialism is advantageous, but in modern medical specialism there are dangers. One is the tendency of the specialist to lose the proper perspective of the patient as a whole. Another is the difficulty of keeping open the lines of communication between specialist and general practitioner. These lines daily become longer and more tortuous. When the vocabulary of any specialty becomes unintelligible to the average medical intelligence, it is in danger of losing its usefulness.

There are two kinds of specialists: the real and the false. Of the pseudospecialists there are examples to be found within the medical profession itself and a still more luxuriant crop of unashamed quacks outside it. He extends his practice mainly by astute canvassing. He has been deservedly pilloried by candid novelists. The pseudospecialist, greedy of notoriety and financial gain, is neglectful of ethical standards and sometimes actually dishonest. We are unhappily familiar with the blatant commercially minded consultoid who performs unnecessary operations on his richer patients for purposes of revenue and on his poorer ones in order to improve his technic. Sometimes he operates in order to accumulate and publish statistics demonstrating his own preeminent skill.

The true specialist is a man possessed of natural aptitude who, after intense training on special materials, sometimes necessitating dexterity in the manipulation of complicated apparatus, gradually attains to such a degree of knowledge and skill that he is deservedly recognized as a guide in difficult and doubtful problems. We have the good fortune to possess many such men.

How are we to recognize the true expert? He has characteristics by which he can be recognized. We observe the readiness with which he submits his results to control, criticism and reobservation by his colleagues. He records his negative results or failures as scrupulously as his successes. He avoids quoting so-called percentages when dealing with short series of figures. The pseudo-expert who has had four or five successful cases claims "100 per cent"

of successes. No one should speak of a percentage until he has had at least a hundred cases from which to quote.

What will be the future of medicine and of specialism? Every medical practitioner must remain a student to the end of his professional career. The day that a medical man ceases to learn, that is the day on which he should retire from practice.

THE FUTURE OF MEDICINE

Some practitioners may for a time succeed in remaining up to date, but after years of busy practice many of us would make a poor show at a professional examination, in competition with our juniors, or even with some of our own pupils. The standard of knowledge of the general practitioner of today often surpasses the peak of certain specialists twenty-five years ago.

It may seem impracticable to make all doctors attend from time to time graduate courses in medicine, surgery and therapeutics. Some of the best men in the profession do so. It is encouraging that a program of this sort has recently been presented by the Ministry of Health as a gift to general practitioners wise enough to take advantage of it. But so long as graduate courses are optional and not compulsory it is chiefly the best type of practitioner who will attend them, while the more obsolescent types will continue to plod along the old roads, obstructing the speedier models which overtake them on the journey.

The family doctor who studies not only the disease but also the patient, who knows his patient's personal circumstances and constitutional tendencies, can never be replaced by the red-tape government official. His level of scientific culture will continue to rise and his functions will become not less but more important. To him it will fall to make the clinical application of scientific advances in the prevention and treatment of disease.

True specialism is essential to the progress of scientific medicine. The specialist of the future, with his superior skill in a restricted field, may expect to continue to be paid on a somewhat higher scale than the general practitioner, but not disproportionately high. This discrepancy will tend to diminish as the specialist finds himself in company with his fellow workers, becoming a cog in the complicated machinery of modern social life.

The leaders of the medical profession in the future will not be drawn almost exclusively, as at present, from its professorial and specialist members. The cultured general practitioner will come increasingly to the front. He will be the natural leader in every health campaign. He will represent his colleagues and his patients.

He will defend their interests with a greater understanding than that of the academic members who now so largely comprise most of our official and deliberative assemblies.

THE DISCOVERY OF HENRY PLUMMER

In the year 1900 Dr. William J. Mayo¹ was called to Racine, Minn., in consultation with Dr. Albert Plummer to see a patient. Dr. Mayo drove the twenty miles from Rochester to Racine to find Dr. Plummer ill in bed. His son Henry, however, who had recently graduated, was in practice with his father and gladly went along to see the patient. The interesting story of this consultation is related here almost entirely in Dr. Mayo's own words. It was arranged, he said, that "I should leave my team of horses and ride the seven miles with Henry, who came out carrying a microscope. During the ride Henry talked to me about the blood, and he had an extraordinary amount of information about its composition, its characteristics and function, much of which I realized was not to be found in print at that time.

"The case we were to see was one of leukemia, of the type at that time called aleukemic leukemia; it is now designated leukopenic leukemia. Henry took a drop of blood from the ear of the patient, put it under the microscope and demonstrated the findings to me. He called in the hired man and a member of the family and took blood from each of them and under the microscope contrasted it with the blood of the patient for my information. On the way back he continued to talk about the blood, and spoke also of his interest in the thyroid gland.

"When I got home that night I told my brother that Dr. Plummer had a son in Racine who certainly knew more about the blood, at least, than any one I had ever met. I thought he was an extraordinary young man, and I believed we ought to try to bring him here and add him to the staff to bring our laboratories up to date. I wrote young Dr. Plummer and asked him to come up to talk with us. He came, we went over the situation, and he came on the permanent staff early in the year 1901.

"Henry took charge of the laboratories, and as a result of his efforts in a few months we possessed as good laboratories, I believe, as far as relation to clinical medicine was concerned, as were to be found elsewhere. In developing the laboratories he always kept the patient in mind. He used scientific apparatus not to take the place of clinical observation but to aid and verify.

¹ Mayo, W. J.: The Work of Dr. Henry S. Plummer, Proc. Staff Meet., Mayo Clin. 13: 417 (July 6) 1938.

"I remember well that Dr. Charlie and I had been greatly impressed with the x-rays and such related mechanisms as were available at that early date, and we had acquired a rather imposing electrical machine. No one knew just what it could do, but it was thought to have some important diagnostic value. Unfortunately machines of this type were sometimes being used by charlatans to impress patients and for that reason we had all the connections of the machine which could be used for spectacular action pulled out and replaced with wooden pegs. We showed this machine to Henry, who was much amused. As he had developed the clinical laboratories, so he took over the x-ray work, and to the day of his death he carried the scars of x-ray burns on his hands.

"In 1889, when St. Mary's Hospital was first opened, in one of the earliest operative cases there was the largest thyroid tumor I have ever seen. The patient, a Scotchman aged about 62, lived near Racine, the home of the Plummer family. The patient had great difficulty in breathing and I knew that, whatever happened, the tumor must come out. While the patient made a good recovery, this was the beginning and end of my work in the goiter field.

"Henry Plummer as a boy knew this patient while at Racine and was familiar with the details of the case. It made such an impression on his mind that he became interested in the thyroid gland and in his college course followed the cases of thyroid disease in the dissecting room and the experimental laboratories. He remained intensely interested in the subject of the thyroid all his life.

"When Henry joined the staff, he was at once struck with the whole question of the purpose of the thyroid gland, its secretion, and its relation to health and disease. He made a special study of disturbances of function of the thyroid and cleared up many of the previously confusing ideas on the subject of thyroid disease. His studies on the effect of iodine in the pre-operative treatment of exophthalmic goiter led to an immediate reduction of the operative mortality in this disease to less than 1 per cent, and the necessity for multiple stage operations was almost eliminated. This elucidation of the role of iodine in the treatment of exophthalmic goiter ranks among the great contributions to medicine.

"The many papers Henry Plummer wrote showed the progressive bent of his mind. He assiduously attended meetings of medical societies for the purpose of gaining information as well as to contribute. Always he concentrated on the fundamentals, the blood, the circulation, the heart, the kidneys and their relationship to the thyroid gland and other glands of internal secretion. Look over the bibliography of his scientific publications. Each article was care-

fully prepared; each carried the work discussed a step further. For thirty-six years there was a continuous development of the subject to which he gave his life.

"In 1899, as chairman of the Section on Surgery of the American Medical Association, I had written my address on esophageal stenosis. In one case of a different type, the obstruction was almost complete, yet there was no history of a cause. I had made a gastrostomy and had discovered that I was able to pass a sound up from below. Henry took over the case, developed the theory of cardiospasm, brought about dilatation of the stricture by the use of esophageal sounds, and cured the patient. He continued in this field with the greatest enthusiasm and developed mechanical methods of removing foreign bodies from the esophagus. From this phase of the study he passed to the investigation of diverticula of the esophagus. He developed bronchoscopy for the removal of foreign bodies in the bronchi, accomplished dilation of bronchial strictures, and worked out the method of diagnosing disease conditions of the lung by securing specimens of involved lung tissue for microscopic examination. His study of oxygen requirements led to the building of airtight glass oxygen chambers. These rooms, which preceded the oxygen tents commonly employed today, are still in use. In this field he achieved extraordinary results. Henry was a genius in mechanical detail. The first Mayo Clinic building, begun in 1912, was essentially his work, in which the architects gratefully acknowledged his leadership. The present clinic building connected with the old is his monument.

"Loved by his confrères and respected by the learned men of the profession the world over, Henry S. Plummer passed away Dec. 31, 1936, at the age of 62. When stricken with bulbar paralysis he recognized what it was and asked to have the family summoned, saying that in an hour he would be unconscious. As long as that intelligence which had carried him through life was permitted to function, he traced the progress of this last illness.

"The life of Dr. Henry S. Plummer was devoted to the welfare of mankind."

How to Become a Diagnostician

The high-developed clinician examines his patients carefully and minutely, he recalls the course of disease in past patients and becomes a prophet of the future course of disease in each new patient; he knows from experience the possibilities and the failures of treatment; he is cool and collected; he plans a campaign of therapy and pursues it day by day, not easily driven from his plan unless new conditions develop. . . . Persistently experience and knowledge are increased; eventually by reason of attainment in experience and knowledge increasingly the physician is sought by other physicians for help in solving their problems; he has become a consultant.—Christian, Henry A.: *The Lure of Medicine*, *Virginia M. Monthly* 65:515 (Sept.) 1938.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

Interns' Contest in Mahoning County, Ohio

Four interns presented case reports before the Mahoning County Medical Society in Youngstown, Ohio, June 21, at the annual Interns Contest sponsored by the society. The first prize of \$15 was awarded to Dr. Densmore Thomas for his paper on "Trichinosis" and the second prize of \$10 to Dr. Donald A. Miller for his report of a case of "Stab Wound to the Left Side of the Chest." The prizes were awarded in consideration of the completeness of the work-up of the case, the significance and teaching value of the case itself, and the manner of presentation. The four papers were so equally interesting that the decision of the five judges was reached on the delivery alone.

Memorial in Africa to Noguchi and Young

A memorial to the late Drs. Hideyo Noguchi and William Alexander Young was formally unveiled by Sir Arnold Hodson at Akkra, Gold Coast, Africa, April 2. A representative gathering of the people of Akkra was present at the ceremony. Before the unveiling Dr. David Duff, director of medical services for the Gold Coast, gave an account of the work of these two medical martyrs. In addition to this memorial a brass plate, suitably inscribed, will shortly be placed in the room of the Medical Research Institute at Akkra, where Noguchi and Young conducted their yellow fever studies. Noguchi had gone to the Gold Coast in British West Africa as representative of the Rockefeller Institute for Medical Research, New York, to complete researches on yellow fever, and he died of that disease at Akkra, May 21, 1928. He was born in Japan and graduated in medicine at Tokyo Imperial University in 1897. Subsequently he worked in the University of Pennsylvania. Young, also one of a scientific party sent to Akkra by the Rockefeller Institute for Medical Research, died there May 29, 1928, of yellow fever. Dr. Young was of Scotch descent and received his medical education in England.

Fellowships Available in Chile

Two fellowships will be available next year to American students for study at the special January session of the University of Chile. These fellowships are offered by the Chilean government and include tuition, 900 Chilean pesos for living expenses, and a pass on the Chilean railroads. In addition the Carnegie Endowment for International Peace has granted \$500 to each fellowship to cover traveling expenses to and from Chile. Preference is given to candidates who have had at least a year of graduate work. Applications are available at the Institute of International Education, 2 West 45th Street, New York City.

Hunterian Professorship Awarded to Canadian

The Hunterian professorship in the Royal College of Surgeons of England has been awarded to Dr. Donald W. G. Murray of Toronto. This is the second time this award has been given to a Canadian professor, the other occasion being in 1924, when Dr. William E. Gallie of Toronto was so honored. The distinction comes to Dr. Murray as a result of his work on heparin, which has been done in conjunction with Dr. Charles H. Best, professor of physiology of the University of Toronto. Dr. Murray will give his lecture in London, England, next year.

Fiftieth Anniversary of Marine Biological Laboratory

The fiftieth anniversary of the Marine Biological Laboratory, Woods Hole, Mass., is being celebrated this year, according to *Science*. A portrait of Mr. Charles R. Crane, New York, who was largely responsible for the growth of the institution, was presented at an informal meeting to celebrate the semicentennial of the laboratory. Mr. Crane was president of the board of trustees from 1902 until 1925; he gave a completely equipped laboratory building in 1914 and later a large sum for an endowment fund. The first building was opened for the use of seven investigators and eight students in the summer of 1888, with Prof. C. O. Whitman, Chicago, as director. The attendance is now more than 500. To the original building, still used for investigation and research, have been added other wooden buildings and a large brick laboratory containing a library, research rooms equipped with running fresh and salt water, chemical and apparatus rooms, an x-ray installation and a large auditorium. A statement of Professor Whitman expresses the aim of the laboratory: "The Marine Biological Laboratory attaches itself to no single institution but holds itself rigidly to the impartial function of serving all on the same terms. . . . The whole policy is national in spirit and scope. The laboratory exists in the interests of biology at large." Recent changes in the staff include the appointment of William W. Ballard, Ph.D., assistant professor of zoology and anatomy, Dartmouth College, Hanover, N. H., and Douglas M. Whitaker, Ph.D., professor of zoology, Stanford University, California, to succeed Lester G. Barth, Ph.D., assistant professor of zoology, Columbia University, and Charles Packard, Ph.D., assistant professor of zoology at Columbia, who resigned from the embryology staff.

Faculty Changes at Oklahoma

The University of Oklahoma School of Medicine, Oklahoma City, has conferred the title of emeritus professor on Dr. Edmund S. Ferguson, professor of ophthalmology; Dr. William M. Taylor, professor of pediatrics, and Dr. John F. Kuhn, professor of gynecology. Dr. Leslie M. Westfall, professor of clinical ophthalmology, succeeds Dr. Ferguson; Dr. Clark H. Hall, associate professor of pediatrics, succeeds Dr. Taylor, and Dr. Grider Penick, associate professor of gynecology, succeeds Dr. Kuhn.

Vermont Now Requires Three Years for Admission

The College of Medicine of the University of Vermont has adopted requirement of three years of college work as minimum for admission. This will take effect next fall.

Miss Helena McMillan Retires

Miss Helena McMillan, a leader in hospital and nursing education and for thirty-five years head of the School of Nursing of the Presbyterian Hospital of Chicago, has announced her retirement as director of that school effective in October. Miss McMillan's work has not been confined to nursing; she has been interested also in hospital administration and the development of better care of the sick in the home as well as in the hospital. The *Journal of the American Hospital Association* points out that she is perhaps the only

person living who participated in the second annual convention of the American Hospital Association in Cleveland, at which time Miss McMillan presented a paper on "The Relationship Which Should Exist Between the Superintendent of the Hospital and the Superintendent of Nurses." Miss McMillan was at that time superintendent of the School of Nurses of the Lakeside Hospital in Cleveland.

Ohio Personals

Dr. Alec Laidlaw Phimister has resigned as demonstrator in medicine at Western Reserve University School of Medicine in Cleveland to enter the practice of medicine in London, England. Dr. Kenton R. Phelps, graduate of Western Reserve University School of Medicine in 1935, was appointed a resident in neurologic and cardiac surgery at the University Hospitals, Cleveland, beginning July 1, 1938. Dr. Carl H. Lenhart, director of surgery in the University Hospitals of Cleveland, has been elected president of the Cleveland Medical Library Association. In addition to being professor of surgery at Western Reserve University School of Medicine, Dr. Lenhart has been "directing librarian" for eighteen years.

Alumni Reunion in Ann Arbor, Mich.

A reunion of the alumni of the University of Michigan Medical School and of the former staff members and interns of the University Hospital, Ann Arbor, was to be held September 29-October 1. Among other speakers were the following:

Dr. Reuben Peterson, Duxbury, Mass., Landmarks in the History of the University of Michigan Medical School and Its Hospital.
Dr. Cyrus C. Sturgis, Ann Arbor, A Résumé of Eleven Years' Experience in Hematology at the Simpson Memorial Institute.
Dr. Donald D. Van Slyke, New York, The Physiology of Renal Excretion.

Dr. Norman F. Miller, Ann Arbor, Common Lesions of the Cervix.

Dr. Ward J. MacNeal, New York, Bacteriophages as Aids in Dealing with Infections.

Dr. Carl E. Badgley, Ann Arbor, A Study of the Causes and Methods of Prevention of Nonunion of Fractures of the Shaft of the Long Bones.

Dr. Walter Bauer, Boston, The Physiology of Normal Joints and Its Relation to Joint Disease.

Bradley M. Patten, Ph.D., Ann Arbor, The First Heart Beats and Circulation of Blood as Shown by Microscopic Embryos.

Dr. . . . Harbor, The Intrinsic Factor in the
Inheritance of Retinoblastoma.

Dr. Joseph Brennemann, Chicago, Abdominal Pain in Children.
Dr. Hugo A. Freund, Detroit, Renal Ischemia and Vascular

Dr. Max M. Peet, Ann Arbor. Results of Splanchnectomy for

Dr. Hugh Cabot, Rochester, Minn., Intravenous Urography: Its

Dr. Francis E. Senear, Chicago. The Serologic Diagnosis of

Dr. Francis E. Seneear, Chicago, The Serologic Diagnosis of Syphilis.
Dr. Frederick A. Collier, Ann Arbor, Physiology and Chemistry

Dr. Frank N. Wilson, Ann Arbor. The Differential Diagnosis

Dr. Frank N. Wilson, Ann Arbor, The Differential Diagnosis of Coronary Occlusion.
Dr. Charles W. Edmunds, Ann Arbor, The Problem of Drug

Dr. Charles W. Edmunds, Ann Arbor, The Problem of Drug
Addiction.
Dr. Warren T. Vaughan, Richmond, Va., Tissue Tension Studies

Dr. Warren I. Vaughan, Richmond, Va., Tissue Tension Studies in Clinical Allergy and Experimental Anaphylaxis.

Dr. James B. Herrick, Chicago, Acute Endocarditis.
Dr. Louis H. Newburgh, Ann Arbor, A New Interpretation of
Diabetes Mellitus in Middle-Aged Obese Persons.

Dr. Perrin H. Long, Baltimore. Further Observations on the Experimental and Clinical Use of Sulfanilamide.

The Relationship Between Them.

Dr. Hiram Winnett Orr, Lincoln, Neb., Methods for the Prevention and Cure of Septicemia Following Injuries and Sur-

Dr. Udo J. Wile, Ann Arbor, Sex Hormone Studies in Acne. The

Dr. Udo J. Wile, Ann Arbor, Sex Hormone Studies in the Urinary Excretion of Androgenic and Estrogenic Substances.

Dr. Frederick G. Novy, dean emeritus of the medical school, was the speaker at the banquet in the Intramural Sports Building. Dr. Bauer and Dr. Richard H. Freyberg, Ann Arbor, conducted a round table discussion on arthritis at a luncheon September 29. The following day a symposium on poliomyelitis was pre-

sent at luncheon. The reunion was to be concluded October 1 at the opening convocation of the medical school when Dr. Francis Peyton Rous of the Rockefeller Institute for Medical Research, New York, was the speaker.

Aid for Study of Vascular Problems

The Taylor Instrument Companies, Rochester, N. Y., gave \$5,000 to further investigation in the field of vascular problems by Drs. Mont R. Reid and Louis G. Herrmann of Cincinnati. This gift will be placed in the Pavaex Appreciation Fund. According to the *Journal of Medicine*, Drs. Herrmann and Reid have given years of altruistic endeavor in their development of passive vascular exercise therapy, and the Taylor Instrument Companies has manufactured the instrument without financial profit. Dr. Reid is head of the department of surgery, and Dr. Herrmann is assistant professor of surgery and director of the vascular clinics at the Cincinnati General Hospital.

Promotions at Vanderbilt

The following promotions at Vanderbilt University School of Medicine, Nashville, have been approved by the board of trustees: Dr. Samuel M. Bloomstein to professor of clinical pediatrics, Dr. Leonard W. Edwards to associate professor of clinical surgery, Dr. Rudolph H. Kampmeier to associate professor of medicine, Dr. Ralph M. Larsen to assistant professor of surgery and anatomy, and Dr. Guy Sydney McClellan to assistant professor of obstetrics and gynecology.

Aid for Pellagra Investigation

The Markle Foundation, New York City, has appropriated \$14,000 to support the investigations of pellagra for a two year period now being conducted by Dr. Tom D. Spies, associate professor of medicine at the University of Cincinnati College of Medicine. The Josiah Macy Jr. Foundation gave \$4,500 to support these investigations until next February.

Prizes for Students at Maryland

A prize of \$25 is given each year by Mrs. Abram B. Gaither, as a memorial to her late husband, to the student in the senior class at the University of Maryland School of Medicine who does the best work in genito-urinary surgery.

Another annual prize of \$25 has been established by Mrs. S. M. Shoemaker and Mrs. B. F. Johnston as a memorial to Samuel M. Shoemaker for the best essay on "Milk in Relation to Public Health," written by a student in the senior class.

Pathologists Appointed at Long Island

Dr. Caspar G. Burn, assistant professor of pathology at Yale University School of Medicine, New Haven, Conn., has been appointed associate professor of pathology at Long Island College of Medicine. Dr. Burn graduated from Yale in 1930. Dr. John Musser Pearce, recently on the staff of the Rockefeller Institute for Medical Research, Princeton, N. J., has been appointed instructor in pathology.

Gift for Gynecology at Pennsylvania

The University of Pennsylvania School of Medicine has received \$50,000 from the estate of Dr. William C. Goodell, who died in 1918. The bequest is to establish the William Goodell chair in gynecology, it was reported.

ERYSIPELOID AS AN OCCUPATIONAL DISEASE

CHAIRMAN'S ADDRESS

JOSEPH V. KLAUDER, M.D.

PHILADELPHIA

The skin disease which Rosenbach in 1884 designated erysiploid is now known to be an infection caused by *Erysipelothrix rhusiopathiae*, the organism of swine erysipelas. My previous reports¹ concerned the infection in swine and in human beings, especially commercial fishermen. The organism was recovered by culturing an excised piece of involved skin from swine and from patients. Bacteriologic studies, serologic reactions and the virulence of organisms recovered from different sources were reported.

My purpose now is a clinical analysis of 100 cases of erysiploid, with particular reference to the occupational nature of the disease. Eighty-eight of the patients were infected through an injury to the hands in the course of employment and were claimants under workmen's compensation laws. The infection is therefore of importance to the industrial physician.

THE ORGANISM AND THE INFECTION IN SWINE

It will suffice now to discuss briefly the organism and the infection in swine. There are three generally accepted strains, human, swine and mouse, although the organism has been found in a considerable assortment of animal species either as a harmless saprophyte or as the cause of disease. Its wide dissemination is extraordinary. It is found wherever nitrogenous substances are decomposing. In putrid material the organism is capable of retaining its viability and virulence for months. In certain environments it exists in the soil as a saprophyte.

The virulence varies considerably in different species and in the same species. The organism has a capacity to change suddenly from a harmless saprophyte to a pathogenic parasite. This transition occurs particularly in swine. Man is relatively immune, particularly when the organism enters through the gastrointestinal tract.

Read before the Section on Dermatology and Syphilology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

V.; Righter, L. L., and Harkins, M. J.: A Distinctive and Severe Form of Erysiploid Among Fish Handlers: Report of Clinical and Laboratory Studies; Demonstration of the Bacillus of Swine Erysipelas, Arch. Dermat. & Syph. **14**: 662-678 (Dec.) 1926. (c) Klauder, J. V., and Harkins, M. J.: Erysiploid in the United States: Clinical and Laboratory Study, J. A. M. A. **96**: 1205-1209 (April 11) 1931. (d) Klauder, J. V.: Generalisiertes Erysiploid: Bericht über einen 29 Monate dauernden Fall mit Sektionsbefund, Dermat. Wehnschr. **98**: 613-619 (May 19) 1934.

In human beings and swine the organism has an affinity for the skin. Pigeons and white mice are highly susceptible to artificial infection; rabbits and guinea pigs considerably less. Field mice are immune (a means of differentiation).

The virulence as well as the appearance of the organism can be modified by serial passages through animals and also by culture. Passage through rabbits increases the virulence for this species but decreases it for swine. Passage through pigeons increases the virulence for all animals. In our studies a three year old culture of a swine strain was no longer pathogenic for white mice and pigeons.

The infection is one of the most serious diseases of swine. It is manifested in three forms. A mild form ("diamond skin" disease), characterized by slight constitutional symptoms and the presence of sharply circumscribed quadrangular, bluish red lesions on the skin; a severe form, characterized by constitutional symptoms of septicemia, the presence of diffuse areas of erythema and at times vesicles, petechia and necrosis, and a chronic form, characterized particularly by polyarthritis (fig. 1) and at times symptoms referable to a vegetative type of endocarditis.

The disease in swine, long prevalent in Europe, has been increasing in the United States. It was first reported here in 1921 but there were only a few isolated cases until about 1930, when an outbreak was reported in South Dakota. Since that year the malady has appeared in practically all states.²

CLINICAL FORMS OF ERYSIPELOID

The disease in man as first described by Rosenbach was a mild, rather localized, cutaneous infection. This is the usual form of the disease and is later discussed. It is now known that the disease may, although rarely, be expressed as acute septicemia with a fatal outcome or as a generalized cutaneous infection with arthritic and constitutional symptoms, the arthritic symptoms predominating somewhat. The latter form is comparable to one form of the infection in swine.

The localized cutaneous form of the disease occurs at the site of epidermal defect on any part of the skin, usually the hands; it is of variable severity, with or without localized arthritic or constitutional symptoms. The first symptom is pain at the site of inoculation and is followed by swelling and erythema. The most distinctive feature of the disease, of considerable diagnostic import, is the purplish red color of the erythema. The erythema slowly progresses (figs. 2, 3, 4 and 5), producing another distinctive feature, a sharply defined, slightly elevated, zone (fig. 2), which extends peripherally as the central portion fades away. The involved

2. Hog Raisers Cautioned Against Swine Erysipelas, Press Service, U. S. Department of Agriculture, Washington, D. C., June 28, 1937.

area is swollen and tense, as though fluid had been injected intracutaneously. If the finger is involved the swelling and tenseness make movement difficult.

Another characteristic of the disease is its migratory nature; new purplish red patches appear at remote areas. If the infection originally involved one finger, eventually all the fingers and the dorsum of the hand or

Fig. 1.—Acute arthritis with erysipelas infection in the swine. Note the swollen condition of the joints, particularly of the front feet, on which the animal refused to bear weight. (From the Bureau of Animal Industry, United States Department of Agriculture, Washington, D. C.)

palm (fig. 3) or both may become affected, the erythema appearing and extension may take place by continuing. The erythema may completely disappear at the areas first involved at the time other areas are affected. The disease involutes without desquamation.

The appearance is not that of a pyogenic infection, with which the condition is frequently confused. The color of the erythema is different, there is no pitting on pressure, and suppuration never occurs. Although itching and tingling are frequently present, pain is the most conspicuous subjective symptom. It is throbbing and burning in character, often preventing sleep. Other features of the disease are discussed in the analysis of cases.

The mildness or severity of infection usually suggests the source of infection; this in turn governs the virulence of the organism. In our studies infection was more severe when contracted from a fish source.³ The virulence of the organism isolated from this source was greater than that isolated from other sources.⁴ From our studies and from clinical observation it appeared that the organisms from the following sources, in the order stated, were the most virulent: (1) partly decomposed fish, (2) live slimy fish, (3) swine, (4) fish in the retail market and (5) other sources.

ANALYSIS OF 100 CASES

Sex.—Of the 100 patients, ninety-three were males. Of the seven females, four were employees in an

3. There is no known disease of fish caused by the organism of swine erysipelas. It appears that the slime of the fish attracts the organism from refuse thrown into the water and other decaying matter and that change of environment increases the virulence.

4. The most virulent strain we isolated from a fish source killed white mice in four days after intraperitoneal injection of the smallest amount employed, 0.0000001 cc. of a forty-eight hour pure culture in hormone bouillon. This compared with the following lethal doses of a forty-eight hour pure culture of the organism from different sources injected subcutaneously into white mice: swine source, the most virulent strain studied, 0.001 cc. killed in five days; rabbit source, 0.01 cc. killed in five days; turtle source, 0.1 cc. killed in five days. Stickborn, quoted by Wilhelm Kolle and August Wassermann (Handbuch der pathogenen Mikroorganismen, ed. 2, Jena: G. Fischer, 1913, vol. 6, p. 12) gave 0.000001 cc. of a forty-eight hour bouillon culture of a swine strain of the organism as the lethal dose for white mice.

abattoir, one was a housewife who was infected while cleaning fish, one was a dressmaker and the remaining one a food handler.

Source of Infection.—The source of infection is evidenced in the occupation of the patient and is shown in the accompanying table. The predominant occupation was work in an abattoir (figs. 2 and 4).⁵ Infection among the employees of abattoirs was not confined to those engaged in slaughtering swine but affected employees handling all parts of the swine, including the bones and pork products. Men engaged in making sausages or scrapple or in handling lard or objects exposed to swine or swine products, such as machinery, boxes, crates and tables were infected. For example, one patient, a driver of a meat truck, cut his finger on the door, and erysipeloid appeared at the site of injury. It is possible that in this and similar cases the organism was present on the soiled hands of the worker rather than on the object injuring the skin.

The next most frequent source of infection was fish. Of sixteen patients infected from this source eleven were engaged in cleaning fish for retail sale (fig. 3), one handled fish in his occupation, one was a housewife and three fished for pleasure and were infected at the site of a cut or puncture wound on the finger.

The student veterinarians were infected when dissecting a dead horse. The patients listed under the occupations connected with tallow and grease included men gathering scraps of meat, fat and bones from retail meat stores and men handling this material in making grease, tallow, fertilizer and chicken feed. The patient listed as a weaver cut his finger when handling wool, and no other source of infection could be determined from the history. The dressmaker pricked her finger when handling spangles on dresses; the source of infection could not be determined. Lard was apparently the source of infection in bakers. One patient,

Fig. 2.—Erysipeloid of eight days' duration in an abattoir employer who cut his thumb while working. Note the sharply defined and elevated border.

a boy, was infected by an opossum. He scraped his knuckles on a rock in the dry bed of a stream and later carried the animal by wrapping its tail around the injured fingers. The food handler, who filled glass jars with such food as India relish and potato salad, had infection appear at the site of a cut caused by a broken glass jar. Crabs and fish cooked at her place of employment were the probable source of infection.

5. In an abattoir in Philadelphia employing about 400 men, the yearly incidence of erysipeloid among the employees was about 2 per cent during the past three years. Dr. Glenn S. Everts of Philadelphia supplied these figures.

Injury.—Epidermal defect plays an important part in inoculation. There was a history of injury at the site at which the infection first appeared in all but five cases in this series. The injury consisted of a cut, puncture wound or abrasion. In one case infection appeared at the site of paronychia and in another at the site of an abrasion caused by cutting the cuticle

Fig. 3.—Erysipeloid of eight days' duration in an employee who was infected while cleaning fish. The fingers, hands and both surfaces of the forearm were involved. Immune serum (30 cc.) was injected intramuscularly, and the infection disappeared. There was no serum sickness. (The two wheals represent a negative test for sensitization to horse serum.)

too close. In nine cases infection occurred despite the application of alcohol, tincture of iodine or mercurochrome at the site of injury immediately or soon after its infliction.

Incubation Period.—The first symptom, usually pain, appeared within twenty-four hours in seven cases, in one day in twenty-four cases, in two days in nineteen cases and in three days in six cases.

Localization and Spread of Infection.—The hand was involved in all cases, and the infection invariably appeared first on one finger. In three cases both hands were involved. In five cases the infection was mild and remained localized in the finger involved. In all other

* Eighty-eight of these patients were infected through injury in the course of employment and were claimants under workmen's compensation laws.

cases the infection progressed, eventually involving different fingers and parts of the hand. The wrist became involved in thirteen cases and the forearms in six (fig. 3).

In one case, which I^{1d} have reported elsewhere, the entire cutaneous surface became involved. Infection started on the finger at the site of injury caused by a stale fish head used for bait. About five months later the infection spread beyond the wrist and gradually involved the skin of the forearm and arm. Despite all variety of treatment there was a gradual spread, and at the end of a year the entire cutaneous surface had

been involved. The extension was wavelike, with the advancing border of erythema always sharply margined. The skin posterior to the advancing border gradually became normal. Areas of erythema would appear and disappear. There were constitutional symptoms, including arthritic manifestations, which are later discussed. The patient became partially incapacitated and depressed and took his life twenty-nine months after the onset of the infection. This generalization of the infection is rare in the literature of the disease.

Vesicles.—One or a few vesicles appeared on the skin at the site of erysipeloid in seven cases. They were hemorrhagic and appeared as the first symptom in one case and soon disappeared. Few textbooks mentioned the occurrence of vesicles with erysipeloid. Such vesicles were not mentioned in Rosenbach's original description.

Lymphangitis and Adenitis.—These symptoms occurred in twenty-one cases. They appear early and disappear before the involved skin becomes normal. In seven additional cases enlargement and tenderness of the regional lymph nodes were noted in the absence of lymphangitis.

Constitutional and Arthritic Symptoms.—Six patients had a temperature ranging from 100 to 102 F. and had mild constitutional symptoms. One patient, infected

Fig. 4.—Erysipeloid of two days' duration in an abattoir employee following a puncture wound by a hog bone. The erythema was well defined and purplish red.

from a fish source, had chills, vomited and had pronounced lymphangitis and a temperature of 101.4 F. Another, infected from a swine source, had similar symptoms, with a temperature of 102 F., and was confined to bed for six days. Some patients stated that they felt ill and feverish the first few days of the infection.

Stiffness of the joints of the involved finger is a common symptom of erysiploid. Such stiffness cannot be attributed entirely to the tenseness of the swollen finger, since it persists after the swelling disappears. At times there is an associated dull pain in the finger joints as well as the wrist (fig. 5), the elbow and even the shoulder.⁶ In ten cases in this series the arthritic symptoms persisted after the skin became normal. In five the joints of one or more fingers were involved and in four the wrist, elbow or shoulder, although in these cases the erysiploid was confined to the hand. In a few cases puffiness around the involved joint was observed. The maximum duration of arthritic symptoms was eight months except in the case in which the infection became generalized. In this case arthritic symptoms were most conspicuous. During twenty-nine months of infection many joints became involved. The symptoms were dull ache, stiffness and loss of full motion, resulting in partial incapacitation. These symptoms were intermittent and were apparently at

Fig. 5.—Erysiploid in a retail butcher who cut his wrist when handling pork. He had lymphangitis, adenitis and pain in his wrist. Immune serum (12 cc.) was injected locally, and there was a pronounced systemic reaction.

first periarticular, resulting from spread of the infection by continuity from the skin. Roentgenograms of the joints at first normal later showed changes.⁷

Relapse and Second Attack.—Relapse occurred in six cases, in four from two to five days after all evidence of the infection had disappeared and in two after two weeks. In two of these cases relapse occurred after local injection of 3.5 cc. and 10 cc., respectively, of immune serum. These figures do not include the case of generalized cutaneous involvement, in which there were many relapses. Only one patient in the series had a second attack, and this occurred at the site of injury four months after the first infection.

6. It is interesting to note the following statement in the report of G. B. Lawson and M. S. Stinnett (South. M. J. 26: 1068-1070 [Dec.] 1933) of 247 cases of erysiploid among workers in a bone factory: "Some of the patients complained of severe pain in the shoulder on the involved side." This was mentioned without reference to the arthritic phase in erysiploid.

7. My experience is similar to that of S. Kartal (Die chronische menschlichen Schweinerotlauf, Deutsche Ztschr. 1935), who said that when the duration of erysiploid was four weeks arthritic symptoms usually disappear with the cutaneous lesions and that when the duration is longer than four weeks such symptoms usually persist after disappearance of the cutaneous lesions. He described three forms of arthritic involvement associated with erysiploid: (1) chronic recidive, arthritic symptoms persisting after cutaneous involution, (2) chronic stationary and (3) arthritis deformans. The third form is identified only from the history.

Treatment.—Rest and heat are important. The hand should be carried in a sling or, as is more preferable, in a splint. Wet or dry heat should be applied a few times daily. All variety of antiseptics and other agents, including foreign protein and roentgen therapy, have been recommended. Calloman⁸ favored a wet dressing of alcohol and also application of ichthammol. Mühlpsfordt⁹ reported favorable results from intensive and repeated use of ultraviolet rays (Kronmayer lamp). Fränkel¹⁰ highly recommended local application of a 3 per cent alcoholic solution of acriflavine hydrochloride, followed by a dressing of ichthammol.

For local treatment I favor constant wet dressing of 12 per cent ichthammol in alcohol. Repeated erythema doses of ultraviolet rays with a water-cooled mercury quartz lamp (Kronmayer lamp) apparently are effective, according to my experience. I am uncertain as to the value of roentgen therapy. Patients to whom I gave such treatment did not do better than the control series. Indeed it is difficult to evaluate different methods of treatment, since in many cases erysiploid apparently runs a self-limited course and splinting the hand may be the only required treatment. To judge by the course of the infection before and after local treatment, I believe that such treatment is effective. I discontinued the routine use of immune serum¹¹ injected either at the site of infection (fig. 5) or intramuscularly (fig. 3). Of forty-eight patients treated with serum, eighteen had serum sickness, and this frequently prolonged the period of incapacitation. I believe that serum is indicated if the infection persists one month, if it progresses rapidly, as in the case illustrated in fig. 3, or if arthritic symptoms are conspicuous. I then use large doses, from 100 to 150 cc. (provided cutaneous testing gives a negative reaction, like that shown in figure 3) injected intramuscularly in the course of a few days. Some of this amount I inject locally. A considerable variety of treatment (detailed elsewhere¹²), including the administration of a total of 450 cc. of serum, was ineffective in the case in which the infection became generalized.

Duration (from Onset to Recovery).—In ten cases the duration was from seven to ten days. Six of the patients were seen early and treated with local infiltration of immune serum (from 6 to 15 cc.), to which therapy the short duration was attributed. In the remaining four cases the infection was mild and was confined to the area originally involved. In another case also the infection was mild and did not spread; the duration was fifteen days. The five patients with a mild infection lost no time from their work, prompt improvement following local application.

The duration was one month in eight cases, forty-five days in one case, and two months, three months and eight months respectively in three cases. The maximum duration was twenty-nine months (at the time of death), in the case of generalized cutaneous involvement. In the remaining seventy-nine cases the duration ranged from ten to thirty days, and in the majority was about three weeks.

ELECTROLYSIS CONTROLLING FACTOR
IN THE USE OF METALS IN
TREATING FRACTURES

CHARLES S. VENABLE, M.D.

AND

WALTER G. STUCK, M.D.

SAN ANTONIO, TEXAS

The use of metals in direct fixation of fractures is a very old procedure. There have been many disappointments and numerous investigations in the effort to find the reasons for the inconsistency of the end results. The factor of electrolysis in bone surgery was but vaguely suggested¹ until we undertook our experiments in 1936.² We undertook to ascertain whether electrolysis was demonstrable, what its effects were on bone and soft tissue, the clinical applications of this principle and finally, through clinical experience, the importance of electrolysis in the direct splinting of fractures with metals.

The initial reports of our experiments were presented before the Texas Surgical Society (October 1936) and the Southern Surgical Association (December 1936) and later published.² The results of further experiments, demonstrating the presence of electric current in vivo when contacts were made with metals in the bone and the early clinical applications of this phenomenon, were presented before the Southern Medical Association (December 1937) and the American Congress of Physical Therapy (September 1937).³ Thus we feel that a comparatively brief review of the further course of study and deductions, with final emphasis on the clinical import of electrolysis, may be sufficient.

CORROSION AND ITS CAUSE

In the search for metals for clinical use in the treatment of fractures, mechanical qualities alone have hitherto been stressed. More recently, however, efforts have been directed toward an attempt to avoid corrosion, since this has become recognized as the cause of changes in bone and tissue as well as of disintegration of the metals used. What is corrosion? It is the disintegration of a metal in its fluid environment. What causes corrosion? The answer is electrolysis. With perfect (100 per cent) freedom from moisture about a metal there is no corrosion, but with any moisture present electrolysis is initiated, as a result of which corrosion begins. To avoid corrosion, therefore, electrolysis must be eliminated, because electrolysis precedes corrosion.

How can electrolysis be prevented? One way is to keep the metal dry and protected from moisture. That is why steel bridges and metal roofs are painted. The other is to use a metal that is passive to its fluid environment or to find a metal that will be passive in certain fluids. Our interest of course is in some metal that will be passive (electrically neutral) in the human body fluids.

Read before the Section on Surgery, General and Abdominal, at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

ELECTRICAL NEUTRALITY VERSUS ELECTROLYSIS

What is meant by the passivity of a metal? The property of protecting itself from the effects of the surrounding moisture. This is accomplished by the instantaneous formation of a molecular veil about the metal as though it were sealed in cellophane. This fact, long a theory, has been proved by an Englishman, Evans, who has been able to remove this "molecular veil" and demonstrate its presence microscopically. Naturally the veil must be constantly present to be effective. If its molecules can be removed by agitation or movement the relative passivity of the metal is changed. This explains why in many instances bone plates and screws of various alloys have caused no disturbance in the body; they have become passified and remained so. Passivity will often result if there is no disturbance of the molecular veil of protection, if the fixation device in the bone is subject to no tissue motion over its surface, which may and does remove the protective veil, or if the metal becomes encysted so that the tissue movements do not affect or change the fluid with which it is in contact.

These phenomena can be effectively demonstrated by using sensitive instruments which will register the current established when a piece of zinc is immersed in

Fig. 1.—The current registered on a micro-ammeter between zinc and silver, contacts in the two femurs of the living animal.

salt solution at the anode and a piece of gold at the cathode. The registered current will soon cease if the gold electrode is kept perfectly still and will be started again if the gold is moved. Any motion of the metal causes the veil to be washed off, and the metal is no longer passive.

If, however, a metal that is inherently passive is substituted for the gold, it may be constantly agitated without producing a current, though the same contacts and solutions are used.

Relative to this work, lack of chemical knowledge and a desire to simplify the discussion have caused it to be stated that after all we are talking about oxidation. On the contrary, our critics have not understood the relationship between electrolysis and oxidation, and these statements have introduced needless confusion. Oxidation is the result of a chemical process involving the increase of positive charges on an atom or the loss of negative charges, and obviously this action must be preceded by electrolysis. Again, if no moisture is present there is no oxidation, just as there is no corrosion. Corrosion and oxidation are separate end results incident to electrolysis. These are electrical and chemical facts which cannot introduce difference of opinion or controversy.

To illustrate, a straight strip of platinum may be immersed in the electrolyte, both terminals then being cathodic, but if the platinum is bent the peak of the bend becomes anodic and current is established to the anode from each cathode. A more homely illustration is that of two galvanized iron nails, one bent, which are exposed equally to moisture. The straight nail will rust more slowly and uniformly because both ends are

Fig. 2.—The absence of current between vitallium and silver, the poles being in opposite femurs of the living animal.

cathodic, while the bent nail will rust first on the convex peak of the bend. At that point, because of the molecular change of its atoms, an anode is created, and at once a current is established from each cathode to the anodic point, with resulting corrosion and oxidation. Finally, it is at the point at which the nail is bent that it will break. It is essential that these basic facts in chemical metallurgy be understood before passivity or electrical neutrality in a metal and the clinical application in the synthesis of bone with metals can be explained.

ELECTROLYSIS IN ALLOYS

In mixed metals or alloys there are great differences in electrical potential between the constituents, and the more metals that are used to create an alloy the greater this difference becomes. Moreover, it is easy to see that there is no way in which a single basic metal can be used commercially. A watch is from 14 to 18 carat gold; a dollar is only 48 per cent silver, and iron is melted and mixed with other metallic ingredients to make it hard or soft, rigid or ductile, as may be desired. In trying to create a strong alloy resistant to the body fluids, one must mix the metals so that there are no corrosive changes and no damage to the bone.

In our studies of electrolysis we deliberately set out to create batteries in the bones of living animals by using screws of mixed metals of different potentials which were not coupled. At autopsy biochemical examinations of the tissues about the screws revealed that ions of one metal had migrated to the neighborhood of another metal in accordance with the law of electromotive force of metals. This proved the presence of the effects of electrolysis. We then tried a number of the so-called rustless and noncorrosive steels in combination with baser metals and in each instance found changes in tissue, necrosis of bone and other electrolytic effects. We found, however, that there were no such effects when one alloy, vitallium, made of cobalt, chromium and molybdenum, was used. Our experiments were repeated several times to check and recheck the apparent fact that this singular alloy seemed consistently to remain inert.

CORROSION OF ALLOYS

In addition to performing animal experiments, we tried to demonstrate the presence or absence of corrosion about these different metals by mounting plates and screws made of them on glass and immersing them in physiologic solution of sodium chloride in sealed glass containers. The solutions in the jars quickly became muddy, and the plates showed the effects of corrosion within a few days. On the other hand, none of these phenomena were present when screws and plates of vitallium were used. The salt solution about the vitallium remained clear for months, with complete absence of corrosion or visual evidence of change in the solution. (Furthermore, we had a piece of vitallium hung off a dock in the Gulf to find out whether the constant wash of the sea would affect its passivity. After a month it was as bright as the day it was immersed.) Chemical examination of the solutions about the plates and screws of the metals other than vitallium revealed positive evidence of the metallic constituents of the metal. The solution about vitallium, however, showed no evidence of any metal from the plates or screws.

All these experiments were repeated by placing a single screw in physiologic solution of sodium chloride and in blood serum. The results were the same visually and by analysis, except in the case of the single screw of V2a or K2a ("Wipla metal"). This showed less visual change in the saline solution, but by analysis its constituent metals were recovered from the solution. The screw of vitallium caused no reaction in the fluids used, and qualitative chemical tests for metals were negative.

It is interesting to review what Haase, in collaboration with Magnus, has had to say⁴ concerning his experiments with rustless steel in the matter of corrosion based on electrochemical action. His work was published about a year and a half after our preliminary report. His observations entirely coincide with ours

Fig. 3.—A, fracture through the site of an old cyst in the bone. B, union without disturbance of the bone; the engagement of the screws is tight four months after correction.

that V2a (18-8 rustless steel), though more resistant than most metals, does not remain passive or electrically neutral and shows evidence of electro-activity and corrosion in salt solution, sea water and body fluids.

With this proof of the presence of electrolysis about the metals commonly used in operations on bones

4. Haase, W., and others: Rustless Steel in Surgery, Arch. f. orthop. u. Unfall-chir.

and of the reactions in salt solution, blood serum and experimental animals, we undertook to demonstrate the amount of electric current involved by means of a micro-ammeter. A piece of silver wire was attached to the cathode and different metal Lane plates in turn to the anode, with physiologic solution of sodium chloride as the electrolyte. When any of the common metal appliances were used, more than 200 micro-amperes was registered. With vitallium, on the other hand, the micro-ammeter registered only two or three micro-amperes at the instant of immersion and immediately reverted to zero, where it remained in spite of agitation. When the poles were reversed and zinc was attached to the anode, with vitallium at the cathode, a slight momentary reversal of current was shown, which immediately disappeared. Even pure gold does not have this remarkable degree of passivity.

ELECTROLYSIS IN LIVING ANIMALS

Finally, to demonstrate the presence of an electric current between metal plates in the bones of a living animal, screws of different metals were placed in the tibia of a rabbit, and contact was made through a micro-ammeter while the body fluids acted as the electrolyte. In each instance except when a vitallium screw was

* In the entire series there was apparently no loosening or disturbance of the bone about any appliance except one screw. This was in the case of the compound fracture of the femur which was still draining.

used a strong current was registered. With vitallium there was a trace of current at the moment of contact, due doubtless to the thermal differences between the point of contact and the screw in the tibia.

We tried, furthermore, to determine whether the distance between the points of contact was of any moment. Holes were drilled in each femur of a rabbit and a silver screw placed in one and a zinc screw in the other. With this distance between the screws more than 200 micro-amperes was produced, while with screws of vitallium and zinc or vitallium and silver in the two femurs, only a momentary trace of current was seen.

When there is an electric current there is heat plus a disturbance in the electrolyte. This explains beyond

question the decalcification about the screws of electro-active (nonpassive) metals and the increased demineralization of bone at the site of plates and screws in old fractures. The changes are demonstrated by the recovery of an excess of calcium from the fluids collected about the area in which such metals have been used.

With the inherent characteristic of constant passivity of this strange alloy, vitallium, shown in all our experi-

Fig. 4.—Interposition of vitallium cap over head of femur in correction of bony ankylosis. Patient ambulatory after eight weeks.

ments, with or without couple, in physiologic solution of sodium chloride, in blood serum and in vivo, we naturally turned to its application in human osteosynthesis. At this time we know of no other metal or alloy except vitallium which is so completely electrically neutral and sufficiently strong to meet our needs but we believe that, with the recognition of electrolysis as the controlling factor, metallurgists may develop others.

We began the use of plates, screws and nails made of vitallium about eighteen months ago, and in the past seven or eight months many surgeons in other parts of the country have undertaken their use. Their operations have been comparatively recent, and we include in our report only cases in which operation was performed three months or more ago, as we are more anxious to know what happens to the bone in the course of time after the insertion of an appliance made of this metal than we are simply to enumerate cases in which vitallium has been used in fixation.

In the accompanying table there are listed fifty-seven cases, including ours and those of five other surgeons, in which vitallium appliances were retained for three months or more. End results as to healing of the fracture were analyzed and the tolerance of this metal by healing bone was observed. It is our conclusion that there has been neither overstimulation of bone growth, with excessive callus, nor demineralization of bone at the fracture sites or about the screws or nails inserted in the bone.

Having proved the presence of electrolysis and its effects as between metals in operations on bone and the absence of pathologic changes in the bone when a metal which is electrically neutral and remains entirely passive *in vivo* is used, we believe that we may give as our opinion that the use of vitallium or any equally inert nonelectrolytic alloy in the fixation of old ununited or malunited fractures or even fresh fractures opens a new approach to this problem. Previously metals were banned in reconstructive operations on old fractures because they were believed to set up infection, to cause

pressure necrosis or in other ways to inhibit bone growth. We have proved that these complications were due to electrolytic destruction of bone about electrically active metals. On the other hand, when we have used vitallium plates, screws or nails in the repair of fractures we have found that perfect fixation has been obtained, there has been no necrosis of bone and the processes of bone repair have taken place promptly without preliminary decalcification. Thus we feel confident that this totally nonelectrolytic alloy will restore metal to a prominent place in all

Fig. 5.—The fixation of a fresh fracture of the patella by transfixion with a vitallium screw. The screw was applied without entering the knee joint.

phases of fracture work and reconstructive operations and will eliminate the need for such compromises as removable fixation or other temporarily applied devices.

1525 Nix Building.

ABSTRACT OF DISCUSSION

DR. EDGAR L. GILCREEST, San Francisco: This study is epoch making. In the search for a metallic substance for the fixation of fractures a substance had to be secured that could be rendered aseptic and would not be irritating to the tissues. That was a difficult problem. In the solution there have been three stages. Surgeons all remember the stage of internal fixation by plates. Sir Arbuthnot Lane of London devised and popularized all kinds and shapes of beautiful plates, which became the rage in 1910; but most of these plates proved irritating, the wounds often became infected and tragedies often followed. In the second stage, or the period of fear, surgeons often did not know whether or not to operate. They felt that anything they did might prove wrong. In the third, or gadget, stage, more and more external traction was used and innumerable inventive geniuses began to attach their names to their various gadgets to pull bones into place. The multiplicity of these mechanical devices is often confusing and frequently complicates the picture in the treatment of fractures. The surgeon should decide very early in the treatment of a fracture whether he will use an open or a closed method, and if he decides on a closed method he has a reliable friend in vitallium, which

the authors' experimental and clinical experience has proved is an ideal metallic substance, tolerated by the healing bone and surrounding tissues.

DR. LEON O. PARKER, San Francisco: From clinical, microscopic and chemical studies of the steel alloys implanted in tissues, it appears with reasonable certainty that none of them are tolerated or can be trusted to be tolerated permanently. I wish to warn clinicians who are using stainless steel wires or other stainless steel instruments that cannot be removed. When a very small caliber wire is used and a number of loops or coils are encircled about the fractured ends of the bone for fixation, union is frequently shown in the early stages of the fracture and there may be very little disturbance of the tissue for a few months although sclerosis and ebonation in the region of the wire appear later and are followed by pathologic fracture due to the metallic substances. Most surgeons have felt that the tissue intolerance of metal was simply a question of toxic metallic ions being given off from the surface of the metal and redeposited in the tissues in the form of oxide, if it was an iron atom; in the case of chromium, which is more soluble, there is no redepositing in the area of implantation. However, with the work of Drs. Venable and Stuck one must come to the conclusion that it is not necessarily a toxic metallic ion but a toxic metallic electron, the electrochemical phenomenon of electrolysis being in direct proportion to the tissue intolerance. Whether the role of pathogenesis is assigned to this electrochemical phenomenon, which of course cannot be separated from the simple chemical nature of the metal, or to the simple chemical nature of the metal does not matter. These studies show that vitallium is a passive metal, electrochemically, when buried in the tissues, and the chapters on implantation of metals for the fixation of fractures and other uses must be rewritten. With this start the use of the proper metals for the replacement of destroyed segments of bone or joints deserves serious consideration for both further research and clinical trial.

DR. C. S. VENABLE, San Antonio, Texas: The question now is not the fear of pressure necrosis or the tissue changes and discolored fluid erroneously thought of as infection. It is now known that such changes are due to electrolysis. One can now understand why metals in the synthesis of bone, used with such variable success, have gone largely out of vogue in favor of autogenous bone grafts, particularly for older fractures which are already atrophic and demineralized. The use of these mechanical appliances, which suffice to hold the fragments, has on too many occasions resulted in loosening screws, broken appliances and nonunion. The screws could be picked out with the fingers, and a terminal result of fibrous union occurred too frequently as a result of progressive demineralization, a factor secondary to electrolysis; metal plates crossing a fracture site fixed by screws, all the appliances of metals of different potentials, brought about these conditions, and the resulting nonunion had nothing to do with pressure necrosis, as heretofore believed. We are sorry that the appliances made of the metals which we have previously used, particularly rustless steel, have not proved to be electrically neutral and so usable for fracture work, because they may be milled so that any appliance can be made and at less cost; but so long as they do not stand up, it is only proper to report our experience in checking these experiments. This cobalt-chromium alloy, which is electrically neutral and causes no disturbance of the tissue, is too hard to be milled and is limited in application because each article has to be separately cast. We feel that the criterion in the matter of osteosynthesis with metals is that the metal must be electrically neutral or entirely passive in the presence of the body fluids and sufficiently rigid and strong to do its part mechanically. Surgeons are fortunate in having this metal, which we have found to be entirely resistant to body fluids, or passive. Metallurgists may develop other alloys which will meet these conditions; the criterion must be that the metal is passive and retains its molecular veil of passivity in the presence of agitation or friction and remains passive *in vivo*. With this principle carried out, we believe that an era of osteosynthesis with metals may be approached with greater confidence in the end results.

THE TREATMENT OF ACUTE INFECTIONS OF THE CENTRAL NERVOUS SYSTEM WITH SULFANILAMIDE

JOSEPHINE B. NEAL, M.D.

NEW YORK

Acute infections of the central nervous system may be roughly divided into those due to viruses and those due to bacteria. Table 1 gives a list of the diseases that are certainly or probably due to viruses. To this list might be added the Guillain-Barré syndrome, which is believed by some authorities to be due to a virus and by others to be due to avitaminosis.

There has been no experimental work giving favorable results with sulfanilamide in the treatment of any of these diseases except choriomeningitis.¹ With this disease it will be difficult to prove such results clinically, as patients presenting the symptoms of lymphocytic choriomeningitis usually recover before the diagnosis is established by laboratory work.

However, there is some hope that a compound of sulfanilamide may be elaborated that will affect the human virus diseases, since Dochez and Slanetz² have shown that a derivative of sulfanilamide is very effective in the treatment of distemper, a virus disease, in dogs and cats. Their work has been corroborated by Marcus and Necheles.³

Although many highly scientific papers have been written on the various compounds of sulfanilamide, it may be well to speak briefly of the relationship between prontosil (the disodium salt of 4-sulfamidophenyl-2'-azo-7'-acetylamino-1-hydroxynaphthalene-3',6'-disulfonic acid) and sulfanilamide.

The chemical referred to in this paper as prontosil (the name of which is to be changed to neoprontosil) is not the same as the earlier, less soluble preparation synthesized by Mietzsch and Klarer.⁴ My associates and I agree with Brown and Bannick⁵ of the Mayo Clinic that the relation of prontosil to sulfanilamide is peculiar and not clearly understood at the present time. As prontosil yields only 11 grains (0.73 Gm.) of sulfanilamide per hundred cubic centimeters of a 2.5 per cent solution, it is difficult to believe that the satisfactory results observed after the administration of from 40 to 100 cc. daily can be attributed solely to the sulfanilamide fraction of prontosil. It would seem that prontosil is capable of producing some other chemotherapeutic action in the body. Recently Barlow⁶ reported that the oral lethal dose of prontosil for laboratory animals was nearly seven times as great as that of sulfanilamide.

Other workers report favorably on the antistreptococcic effect of prontosil administered orally. With these statements our experience inclines us to agree.

From the Bureau of Laboratories, Department of Health, New York City.

The Winthrop Chemical Company supplied their products for clinical and experimental use.

While we have not used prontosil orally as much as sulfanilamide and prontosil by injection, we have had rapid and remarkable improvement following the use of prontosil by mouth.

In spite of all the work that has been done with sulfanilamide, prontosil and various other compounds, there is still considerable difference of opinion with regard to the proper dosage, the best compounds and the best route of administration.

We have always used a much smaller dose than has been recommended by certain authorities. Indeed, recent experimental work by Osgood⁷ would seem to indicate that small doses at frequent intervals are more effective than larger doses at longer intervals. As a rule we have given 5 cc. or less of the prontosil solution every four hours to young children and 10 cc. every four hours to older children and adults. In addition from 5 to 15 grains (0.32 to 1 Gm.) of sulfanilamide has been given every four to six hours. The same dosage was followed when prontosil was given by mouth. At present we are inclined to use prontosil orally unless the patient cannot swallow or

retain medication given by mouth, under which conditions it is given by injection. We occasionally administer prontosil intraspinally, using an equal amount of prontosil (2.5 per cent) and a specific serum, if available, or sterile physiologic solution of sodium chloride or sterile distilled water. It should be pointed out that the p_H of prontosil is now 6.8, which is compatible with its intraspinal use.

While sulfanilamide is a therapeutic agent of great value, it has toxic effects of more or less importance. The most serious are those associated with the hematopoietic system; namely, hemolytic anemia and agranulocytosis. The development of morbilliform rashes and fever are less serious. Mild toxic effects are quite common, and they include cyanosis, dyspnea, dizziness, nausea, headache, excitement and confusion. Certain of these reactions appear to be direct toxic effects of the drug, while others, particularly hemolytic anemia and agranulocytosis, must be regarded at present as idiosyncrasies. Fortunately, we have not encountered any of the more serious reactions.

With the development of the more severe toxic manifestations the drug should be withdrawn at once. We

7. Osgood, E. E.: *Culture of Human Marrow: Studies on Mode of Action of Sulfanilamide*, *J. A. M. A.* 110:349 (Jan. 28) 1938.

do not, however, consider cyanosis as an indication to discontinue the administration of sulfanilamide. It should be noted that the oxygen-carrying capacity of the red blood cells is not diminished during the period of cyanosis. Dyspnea, which is due to acidosis, can usually be prevented by the routine administration of sodium bicarbonate in conjunction with the sulfanilamide. When the alkali cannot be given by mouth, one may administer a one-sixth molar solution of sodium lactate by the intravenous or subcutaneous route.

It is important in administering sulfanilamide to make frequent, complete blood counts.

Sulfanilamide has its greatest value in the treatment of diseases of the central nervous system due to bacteria. These are, of course, primarily meningitis and infections of the accessory sinuses and mastoids which may lead to meningitis and to brain abscesses. Our experience has been greatest in the field of meningitis. Table 2 shows the distribution by age and

TABLE 2.—Cases of Meningitis According to Age of Patient and Etiologic Agent*

| Age | Meningococcus | Streptococcus | Pneumococcus | Bacillus Influenzae | Bacillus Tuberculosis | Miscellaneous Organisms | Total |
|-------------------------|---------------|---------------|--------------|---------------------|-----------------------|-------------------------|-------|

* During 1937, 147 additional cases of meningitis were observed.

etiologic agent of our cases of meningitis over a long period of years. Since this table was prepared we have observed about 200 additional cases of meningitis.

With regard to infections with the meningococcus, I am of the opinion that serum should be used intraspinally in conjunction with some form of sulfanilamide, preferably prontosil, given either orally or hypodermically. Experimentally it has been shown that a combination of serum and sulfanilamide is more effective than either agent alone.⁸ I realize that Schwentker⁹ and others have reported favorable results in the treatment of meningococcic meningitis with sulfanilamide only. From a somewhat limited experience I do think that sulfanilamide may replace the use of serum in the treatment of meningococcemia.

During the past five or six years there has been a decided increase in meningitis due to *Bacillus influenzae*. Povitzky¹⁰ found experimentally that mice were effectively protected against lethal doses of the strain *B. influenzae* commonly associated with meningitis by the use of prontosil and a specific serum.

With this form of meningitis the clinical results have not corresponded with the experimental results. In treating this form we have used the specific serum intraspinally and also, as bacteremia is often present, intravenously. Recently we have been combining the serum with prontosil for intraspinal use. Sulfanilamide is given also, by other routes. The results, however, have been disappointing. Of eighteen patients only two have recovered.

It has been reported that sulfanilamide combined with serum was as efficacious experimentally with certain strains of pneumococcic infections as with hemolytic streptococcus infections. Our clinical results have not corroborated this observation in the case of pneumococcic meningitis.

Pneumococcic meningitis was uniformly fatal in our experience of nearly twenty-seven years until we began the use of sulfanilamide. Since that time we have had thirty-three cases with six recoveries and one under observation. The recoveries were from types XXXI, XXIX, IV, XIII, VI and VII. The patient with type VI received rabbit serum also. The patient with type VII received horse serum. It should be pointed out that in several of the fatal cases the course was prolonged, with periods of improvement. When a specific serum is available it is combined with prontosil and injected intraspinally. It has seemed to us that one reason at least for the relative lack of success of sulfanilamide in the treatment of pneumococcic meningitis is that foci of infection have been so seldom located and removed. We have seen the recovery of two patients with meningitis for whom the hospital reported the type II pneumococcus.

We have also observed a certain group of cases that may be classed as miscellaneous. Some of the patients had a brain abscess and meningitis, the latter being due in one case to a hemolytic streptococcus, in another to *Staphylococcus aureus* and in a third to a mixed infection. In a fourth case there was a brain abscess due to *B. influenzae* without meningitis. The patients all died. In a fifth case of brain abscess following otitis media and mastoiditis, in which *Streptococcus hemolyticus* was isolated, recovery took place. The patient had received sulfanilamide during the acute phase of the otitis media and also before and following the operation on the mastoid and the abscess. She made a complete recovery without the development of meningitis.

The use of sulfanilamide in cases of hemolytic streptococcus meningitis has yielded the most revolutionary results. Before this chemical was used the case fatality was more than 95 per cent. Since its use the rate has been less than 20 per cent in a group of twenty-seven cases. Table 3 shows the outstanding features of these cases with the exception of the twenty-seventh, which is still under observation. The diagnosis was definitely established by recovery of the hemolytic streptococcus from the spinal fluid by culture. In this connection it is important to stress that certain strains of this organism hemolyze only horse blood and in mediums which do not contain sugar. Unless this is borne in mind, the hemolytic streptococcus will occasionally be misinterpreted as belonging to the non-hemolytic group.

It will be noted that sulfanilamide was used less than twelve hours in two, and less than twenty-four hours in one, of the five fatal cases. In the fourth fatal case the necropsy showed herniation of the cerebellum

through the mastoid wound and thrombosis of the left lateral and transverse sinuses and of the left jugular vein.

These results seem little less than astounding to us who have been working so long and so unsuccessfully

In addition I should like to refer to two cases of meningitis following otitis and mastoiditis, in which the spinal fluid was that of meningitis, with gram-positive diplococci on smear but negative cultures. Both the patients recovered.

TABLE 3.—Cases of Meningitis Due to the Hemolytic *Streptococcus*

| Case | Sex | Age, Years | Primary Source of Infection | Treatment | Result | Comment |
|------|-----|------------|---|--|-----------|---|
| 1 | ♀ | 21 | Maxillary sinusitis on right, otitis on right with mastoiditis | Drainage of antrum, mastoidectomy, spinal drainage, sulfanilamide, convalescent scarlet fever serum | Recovered | Only a small amount of serum was given |
| 2 | ♀ | 7 | Otitis on left with mastoiditis | Mastoidectomy, spinal drainage, sulfanilamide | Recovered | |
| 3 | ♂ | 5½ | Otitis on left | Antimeningococcus serum (4 doses), spinal drainage, sulfanilamide | Recovered | |
| 4 | ♀ | 43 | Otitis on right | Spinal drainage, sulfanilamide | Recovered | |
| 5 | ♀ | 3½ | Otitis on left | Spinal drainage, sulfanilamide | Recovered | |
| 6 | ♀ | 11 | Otitis on right with mastoiditis | Spinal drainage, sulfanilamide | Recovered | Refused operation and mastoiditis persisted after recovery from meningitis |
| 7 | ♀ | 2 | Double otitis with mastoiditis on right, following scarlet fever | Mastoidectomy on right with ligation of right jugular vein, spinal drainage, sulfanilamide, convalescent scarlet fever serum | Died | Meningitis appeared 7 days after operation; necropsy showed herniation of cerebellum and thrombosis of left lateral and transverse sinuses and of left jugular vein |
| 8 | ♂ | 5½ | Otitis on left with mastoiditis, following pneumonia | Mastoidectomy, antimeningococcus serum, spinal drainage, sulfanilamide | Recovered | |
| 9 | ♂ | 8 | Otitis on right with mastoiditis | Mastoidectomy 1 month prior to meningitis, spinal drainage, sulfanilamide | Recovered | Mastoidectomy done about 1 month before onset of meningitis; spinal fluid showed positive culture for 14 successive days |
| 10 | ♀ | 4 | Otitis on left with mastoiditis, and later otitis on right | Mastoidectomy on left, spinal drainage, sulfanilamide | Recovered | At operation left mastoid found necrotic, although no clinical signs |
| 11 | ♂ | 35 | Pansinusitis | Antimeningococcus serum, spinal drainage, sulfanilamide | Died | Sulfanilamide was used for less than 24 hours; necropsy showed pansinusitis and sarcoma of pituitary |
| 12 | ♀ | 12 | Otitis on left with mastoiditis | Mastoidectomy, spinal drainage, sulfanilamide, 1 dose antimeningococcus serum | Recovered | At operation mastoid found necrotic, although no clinical signs |
| 13 | ♀ | 10 mo. | Double otitis with double mastoiditis | Mastoidectomy, spinal drainage, sulfanilamide | Died | Clinical evidence of brain abscess; at operation, dural plate found nearly destroyed; sulfanilamide used for less than 12 hours |
| 14 | ♀ | 8 | Otitis on left with mastoiditis | Mastoidectomy, spinal drainage, convalescent scarlet fever serum, sulfanilamide | Recovered | At operation mastoid found necrotic, although no clinical signs |
| 15 | ♀ | 6½ | Otitis on right with mastoiditis | Mastoidectomy, spinal drainage, sulfanilamide | Died | Necropsy showed meningitis but no localized suppuration |
| 16 | ♂ | 4 | Following measles, otitis with mastoiditis first on left and later on right | Mastoidectomy first on left and later on right, spinal drainage, sulfanilamide | Recovered | Meningitis appeared 12 days after mastoidectomy on left; at this time a mastoidectomy on right was done |
| 17 | ♂ | 7 | Double otitis with double mastoiditis following scarlet fever | Mastoidectomy first on left and 3 weeks later on right, spinal drainage, sulfanilamide | Recovered | Onset of meningitis was about 12 days after the second mastoidectomy |
| 18 | ♀ | 11 mo. | Infection of upper respiratory tract | One spinal drainage, antimeningococcus serum, sulfanilamide | Died | Death in less than 12 hours after receiving sulfanilamide |
| 19 | ♀ | 6 | Double otitis, double mastoiditis | Double mastoidectomy, spinal drainage, sulfanilamide | Recovered | |
| 20 | ♀ | 8 | Chronic otitis on left | Spinal drainage, sulfanilamide orally, prontosil intramuscularly and intraspinally, mastoidectomy | Recovered | Mastoid at operation showed granulation, but no pus; blood culture sterile |
| 21 | ♂ | 2 | Otitis on right | Spinal drainage, sulfanilamide | Recovered | No signs of mastoiditis |
| 22 | ♂ | 15 | Bilateral chronic otitis | Spinal drainage, sulfanilamide, mastoidectomy on left and 2 months later on right | Recovered | Meningitis cleared up shortly after first operation |
| 23 | ♂ | 7 | Otitis on right and mastoiditis | Spinal drainage, sulfanilamide, mastoidectomy | Recovered | |
| 24 | ♀ | 12 | Otitis on right | Spinal drainage, sulfanilamide orally and intravenously | Recovered | |
| 25 | ♀ | 11 | Otitis on right | Spinal drainage, prontosil intramuscularly and intraspinally, prontosil orally | Recovered | |
| 26 | ♀ | 7 | Throat infection | Spinal drainage, prontosil intramuscularly, sulfanilamide orally | Recovered | Roentgenogram of sinuses and mastoid negative |

with this form of meningitis. The question is sometimes raised as to the possibility that the hemolytic streptococcus may recently have become more benign. Such a radical and sudden change seems to us improbable. During the year 1936 we saw twenty patients with this type of meningitis, all of whom died with the exception of one who had had scarlet fever and who was treated with small amounts of sulfanilamide and large amounts of convalescent serum.

I consider sulfanilamide and its various compounds, especially prontosil and prontosil soluble, one of the major achievements in chemotherapy. It has been used too short a time for one to feel certain of the best dose and mode of administration. The full scope of its use in various bacterial infections is not yet known. Indeed, in spite of all that has been done, the drug is still in its infancy. One cannot look forward into the future to see what new developments

may take place in the next few years or even months. The intensive research work which is being carried on makes it quite certain that there are new and important developments yet to come.

ABSTRACT OF DISCUSSION

DR. R. CANNON ELEY, Boston: At the Infants' and Children's hospitals of Boston we have been interested in this new agent and have had the opportunity to administer it in certain infections of the central nervous system. The results have been in accord with those which have just been reported. Dr. Neal has roughly divided these infections into two groups, namely those due to virus invasion and those due to invasion by bacteria. I shall confine my remarks to the value of the drug in certain of the bacterial infections of the central nervous system. During the ten year period prior to the use of sulfanilamide, 118 patients with meningococcic meningitis received antimeningococcus serum therapy with a mortality rate of 39 per cent. Since the introduction of the dye, thirteen patients have been treated by this drug alone with only two deaths. The two patients that died were both suffering from a type II meningococcus infection. During the same ten year period, ninety-two patients with hemolytic streptococcus meningitis were treated by the usual methods and of this group there was only one recovery. These results are in sharp contrast with those obtained since the introduction of sulfanilamide, for we have now treated six patients with six recoveries. Seventy-three patients with pneumococcic meningitis have been admitted to the hospital, and of this group forty-three received specific serum therapy and only one recovered; this patient had a type XII infection. Six patients with pneumococcic meningitis were treated with the usual dose of sulfanilamide, and all died. That larger doses than we have used may bring about a reduction in the mortality rate has been suggested by the work of Finland, at the Boston City Hospital, who has reported ten cases of pneumococcic meningitis treated by the combined use of specific serum and sulfanilamide, with six recoveries. In each of these cases the dosage employed was sufficient to produce a concentration of from 25 to 35 mg. per hundred cubic centimeters in the cerebrospinal fluid. Ninety-six patients with influenzal meningitis have been treated with specific serum and of this group there were six recoveries; six additional patients have received combined serum and sulfanilamide treatment with no recoveries; one other patient received sulfanilamide in amounts sufficient to produce a concentration of 25 mg. per hundred cubic centimeters in the cerebrospinal fluid and recovered. The fact that this patient recovered has suggested that better results might be obtained if larger amounts of the drug were employed in the treatment of this form of meningitis. The methods which we have employed in the administration of sulfanilamide in meningitis have varied as our knowledge of the drug has advanced. When first introduced as a therapeutic agent it was given intrathecally as well as by mouth and by hypodermoclysis, as the case indicated, but since it has been shown that following oral administration the concentration of sulfanilamide in the cerebrospinal fluid is nearly equal to that in the blood stream, intraspinal treatment has been discontinued. In those instances in which the drug cannot be given orally we have resorted to the subcutaneous or intravenous injection of an 0.8 per cent solution of the basic salt in physiologic solution of sodium chloride.

DR. H. W. WOLTMAN, Rochester, Minn.: I shall confine my remarks to meningitis and closely related disorders caused by the streptococcus. Before the application of sulfanilamide in treatment, the mortality rate from streptococcic meningitis was 95 per cent. The treatment involved the most energetic measures that physicians could devise and patients could endure. Indeed, it so happened in our cases that those patients recovered who had had the simplest method of treatment, namely repeated spinal punctures. We had often heard of good results that were attributed to this or that method of treatment, but when such reports concerned larger series of cases there was usually lacking a demonstration of the causative organism. I need not say that the lack of such bacteriologic studies represents a crucial omission. Against the background of a mortality rate of 95 per

cent, Dr. Neal places the new figure of 20 per cent, a result achieved largely by the intelligent use of sulfanilamide. I need hardly mention such technical advances in the treatment as the insertion of a urethral catheter for purposes of controlled drainage and medication, as described by Dr. Love. This I have found very helpful. As with any new method of chemotherapy, the introduction of related drugs and the details of their administration remain to be worked out as our experience with them grows. Dr. Neal previously stressed another point in treatment, namely the attention that foci of infection, particularly in the mastoid process, deserve. Since she made this suggestion my associates and I have not hesitated to employ any additional surgical measures that seemed advisable even when patients were critically ill. Our experience parallels hers, and we stand ready to endorse her contention in this respect. The association of brain abscess with meningitis raises some interesting points. We have seen abscesses develop after streptococcic meningitis apparently had been brought under control. In one case rupture of the abscess into the ventricle occurred, but operation and the continued administration of sulfanilamide led to recovery. Sulfanilamide can hardly be expected to be helpful when diseased regions are out of its reach. This occurs when extensive thrombosis and infection are associated, but it is conceivable that with additional surgical treatment better results may be achieved even here. Dr. Neal speaks on the basis of an almost unparalleled experience. She has supplied us with a reliable background of things as they were and has helped to orient us with regard to things as they are developing.

DR. JOSEPHINE B. NEAL, New York: I am grateful for the suggestion that very large doses of sulfanilamide may be more effective in pneumococcic and influenzal meningitis than the smaller doses that I have been using. I shall try that in the future and hope to parallel the results which Dr. Eley has described.

HEPATITIS

SOME FORMS NOT COMMONLY RECOGNIZED

JAMES F. WEIR, M.D.

ROCHESTER, MINN.

A physician who has many contacts with the medical and surgical aspects of biliary and hepatic disease soon encounters surprises and embarrassments occasioned by the fact that hepatic disease, either as a complicating factor in extrahepatic biliary obstruction or as an independent entity, often comes on unawares. Thus, while in the majority of cases sufficient symptoms and signs are present to permit a diagnosis of obstruction of the common duct or of primary hepatic disease, there is a certain number of cases wherein the two conditions cannot be distinguished readily and the fundamental disease is misinterpreted. Moreover, in certain cases of primary hepatic disease the syndromes present are those commonly encountered in association with surgically relievable obstruction of the common duct. Furthermore, in cases of cholecystitis with stones and obstruction of the common duct (most frequently due to calculus) there may be associated hepatic disease which may readily be overlooked and which may have a significant part in the course of the patient's illness either before or after surgical procedures. In chronic cases this associated disease may be extensive chronic atrophy of the liver, and in cases of acute obstruction of the common duct the associated disease may be varying degrees of acute hepatic degeneration. These conditions often do not receive sufficient emphasis.

In the absence of jaundice, the occurrence of ascites, pruritus, enlargement of the liver or spleen, hematemesis

From the Division of Medicine, the Mayo Clinic.
Read before the Section on Gastro-Enterology and Proctology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

or melanoderma may indicate the presence of hepatic disease. However, there are many hepatic conditions in which these symptoms or signs are absent and in these instances diagnosis must rest largely on suspicion. In a considerable group of systemic diseases, such as the infectious processes, toxemias and neoplastic and leukemic infiltrations, it is generally recognized that the liver may be involved, yet in many instances the hepatic involvement is not suspected and in most instances the full extent of the damage is not appreciated at the time of the illness because of the lack of any of the usual symptoms of hepatic disease. In addition, there are other cases of hepatic disease without jaundice, unassociated with other systemic disease, wherein the possibility of hepatic involvement is not considered and the true nature of the disorder is not recognized.

Recognition of these facts, a healthy suspicion of the possibilities of such conditions as have been mentioned, and the judicious use of hepatic functional tests will aid greatly in demonstrating hepatic disease that is unsuspected or asymptomatic but which, nevertheless, is of considerable significance. When the presence of hepatic disease has been demonstrated, the functional tests aid materially in evaluating the degree of damage and in indicating the prognosis. This perhaps applies particularly to those conditions wherein surgical procedures are contemplated.

In this discussion the term "hepatitis" is used in a noncommittal manner to denote diffuse processes involving the liver and it may include such changes as cloudy swelling, fatty or other types of degeneration, atrophy and necrosis of varying type or degree. Fibrosis and even nodular regeneration may or may not be associated. The material is presented under the following titles, and short reports of cases are used to illustrate some of the forms of hepatitis not commonly recognized: (1) hepatitis associated with diseases of the gallbladder and biliary tract, (2) hepatitis associated with syphilis and its treatment, and (3) hepatitis without jaundice.

HEPATITIS ASSOCIATED WITH DISEASES OF THE GALLBLADDER AND BILIARY TRACT

Primary hepatic disease may mimic perfectly certain disorders of the extrahepatic bile passages, notably those caused by stones. Conversely, the secondary hepatic damage caused by stone and infection may be completely masked by the features of mechanical obstruction to flow of bile.

CASE 1.—A man aged 46, a moderate partaker of alcohol, had suffered for fifteen years from gaseous dyspepsia and attacks of pain of varying severity and increasing frequency in the right upper abdominal quadrant. These attacks were at times associated with chills and fever. A severe attack led to the patient's hospitalization. For twenty years dyspnea without orthopnea had been progressively developing. Edema of the ankles had been present for two weeks. On examination severe pain was evident. The temperature was 104 F. The right upper quadrant of the abdomen was moderately rigid and tender. Moderate jaundice was first noted on the day of admission. Laboratory investigations revealed a leukocyte count of 27,400 per cubic millimeter of blood, marked macrocytosis, bilirubin of 6.2 mg. per hundred cubic centimeters of serum, a direct van den Bergh reaction, cholesterol of 214 mg. and cholesterol esters of 103 mg. per hundred cubic centimeters of plasma, and serum proteins of 5.5 Gm. per hundred cubic centimeters. The albumin-globulin ratio was 1/1.6, and the excretion of hippuric acid was 0.37 Gm. At exploration a small hobnail liver and slight ascites were found.

This patient presented the syndrome commonly attributed to the presence of stone in the common duct.

namely recurring colic, chills, fever, jaundice and leukocytosis. Exploration was carried out on the basis of this diagnosis although it did not explain the dyspnea and edema. There were no cardiac, renal or pulmonary pathologic changes to account for these symptoms. The slightly lowered concentration of serum protein, the reversal of the albumin-globulin ratio and the decreased excretion of hippuric acid indicated hepatic disease. Although primary hepatitis masquerading as a calculus of the common duct is not a frequent occurrence, in our experience at the Mayo Clinic it has been noted sufficiently often that we feel somewhat more emphasis should be placed on such a possibility and on the results of hepatic functional tests.

A similar situation exists in cases in which jaundice is present and calculous cholecystitis has been demonstrated definitely by roentgenologic or other methods. In these instances the possibility of calculi being present in the common duct is considerably enhanced. Mild and transitory disturbances of the liver, as determined by functional tests, are not uncommonly encountered after acute cholecystitis or even biliary colic and are well recognized. The evidence is obtained chiefly by the rate of excretion of bromsulphalein or similar dyes and the character of the van den Bergh reaction. Clinically, the disturbance may be manifested by mild, transient jaundice. More advanced stages of hepatitis are also encountered and should be more frequently suspected, especially in the presence of long-standing cholecystitis or, if there is an enlarged liver, considerable decline in general health and jaundice of short duration. Enlargement of the liver often is accompanied by some splenomegaly. Other clinical symptoms previously mentioned may be present and increase the evidence of significant hepatic disease. In many of these cases the liver may appear to be in surprisingly good condition at operation whereas in others it is markedly cirrhotic and the postoperative course unsatisfactory. Whether or not surgical operation should be undertaken in these cases is frequently a difficult decision to make. Factors which influence this decision are the general condition of the patient, the degree of trouble the gallstones are producing and the evaluation of reserve capacity of the liver by the use of the various hepatic functional tests. Abnormalities elicited by these tests caution the physician concerning increased operative risk, necessity for prolonged preoperative preparation and the possibility of an unfavorable prognosis.

Two complications that may arise in the course of calculous obstruction of the common duct are acute degenerative conditions and chronic hepatitis. The following case is an example of the former:

CASE 2.—A man aged 43 had suffered from biliary colic during the preceding three years. The last attack had occurred ten days before his admission and was followed by persisting jaundice. Deep jaundice and slight tenderness in the right upper quadrant of the abdomen were evident on examination. Laboratory examinations disclosed small amounts of bile entering the intestine, a concentration of serum bilirubin of 19.7 mg. per hundred cubic centimeters, a direct van den Bergh reaction, normal galactose tolerance and a value for blood cholesterol of 340 mg. per hundred cubic centimeters. At operation a thick walled and distended gallbladder, containing pus and "white bile," without stones, was found. The common bile duct was dilated and from its lower end a stone 1.2 cm. in diameter was removed. A T tube was placed in the common duct for drainage. Hepatitis, grade 4, was present. The liver was described as brownish purple and the lobules stood out as punctate areas. Postoperatively, bile drained in rather large amounts (from 750 to 1,000 cc. daily). On the fifth day the

patient became rather drowsy but improved following intravenous administration of dextrose solution. There was a slight rise in the concentration of serum bilirubin, followed by a gradual fall to 4.3 mg. per hundred cubic centimeters on the fifteenth day. Six months later excretion of bromsulphalein was normal and the concentration of serum bilirubin was 2 mg. per hundred cubic centimeters. The patient has remained in good health.

Acute degeneration of the hepatic parenchyma in the presence of calculous obstruction of the common duct has not received the emphasis it deserves. Its severity may vary considerably. It may be mild, as in case 2, or it may be manifested as rapidly fatal acute yellow atrophy terminating within a few days after the onset of symptoms of obstruction and before surgical relief can be attempted. The depth of the jaundice, as evidenced by the concentration of serum bilirubin, is the simplest and most direct evidence obtainable. In the absence of complete obstruction of the common duct in case 2, the high value for serum bilirubin enhanced the evidence that hepatic damage was present in addition to simple obstruction. This was confirmed by the surgical observations and by the symptoms of mild hepatic insufficiency encountered in the postoperative course. As a rule, in cases of stone in the common duct the concentration of bilirubin in the serum does not rise above 10 to 12 mg. I¹ found that in 70 per cent of a series of 102 cases of stone in the common duct the concentration of bilirubin in the serum was less than 10 mg. per hundred cubic centimeters. The higher the value for bilirubin in the serum, the greater is the probability of hepatic injury. Risk of surgical intervention in these cases, if the concentration of bilirubin in the serum is 30 mg. per hundred cubic centimeters or more, especially if the bile duct is incompletely obstructed, is high. It is safer to treat the damaged liver and to await a more favorable time for intervention. On the other hand, obstruction of the duct is the primary difficulty and the sooner the obstruction can be removed without undue risk the better. Often there is considerable difficulty in evaluation of the conditions found and determination of the safest procedure. Clinical experience probably should be the final guide, but the results of liver functional tests should not be ignored.

In cases of chronic, intermittent obstruction of the common duct, hepatic changes commonly occur and likewise are of chronic nature. Usually such cases present chronic obstructive, or secondary, biliary cirrhosis. Pathologic changes are attributable to infection ascending the bile ducts. The usual manifestations are moderate enlargement of the liver and spleen, mild, persisting jaundice with acute exacerbations, pruritus and melanoderma, and these do not in themselves contraindicate surgical intervention. If such changes are not too advanced the patients usually tolerate surgical operation fairly well and often the hepatic changes undergo remarkable resolution. However, the presence of ascites or edema indicates a more advanced stage and is an unfavorable sign. In some instances the concentration of serum proteins or the colloid osmotic pressure of the blood may be fairly normal and other functional tests may present few alterations. Although some patients who present these signs also have excellent recuperative power, nevertheless our experience with such cases has not been happy.

Another form of hepatitis at times associated with calculus of the common duct is chronic atrophy or cirrhosis, often with varying degrees of "adenomatous" regeneration. This apparently is not attributable to ascending infection, because pathologically there is little evidence of ascending infection. The hepatic condition is similar to that in case 1 but the element of obstruction of the common duct also is present. Functional tests may aid materially in demonstrating the former. Even with such evidence one would hesitate to deny such patients relief of the obstruction unless clinical evidence of advanced hepatic disease is prominent.

HEPATITIS IN THE COURSE OF SYPHILIS AND ITS TREATMENT

CASE 3.—A woman aged 40 was first seen at the clinic in 1928 for deafness of seven years' duration. The liver was found to be slightly enlarged. The blood and spinal fluid were strongly positive for syphilis. A diagnosis was made of syphilis of the central nervous system. Treatment was carried out faithfully. In September 1934 tests performed on the blood gave the following results: Kline, 1+; Kahn, 1+; Hinton, positive; Wassermann (Kolmer modification), negative. Tests of the spinal fluid resulted thus: Wassermann, negative; Nonne, negative; cells, 1 lymphocyte; colloidal gold curve, 000,000,211,000,000. No treatment was given during the period from 1934 to 1936.

In January 1936 the patient returned because of an illness of three weeks' duration, characterized by impairment of appetite, fulness and distress in the epigastrium after eating, belching, nausea, occasional emesis and loss of weight and strength. The liver extended from three to four fingerbreadths below the costal margin and the spleen was palpable. Serologic tests of the blood revealed Kline, ±; Kahn, 2+; Hinton, positive; Wassermann, negative. The bromsulphalein test of liver function revealed retention of dye, grade 4, and the van den Bergh reaction was direct. The patient was given a high carbohydrate diet, sodium phosphate and mercury. In February she reported that her condition had improved. In April she felt and appeared much better. With the clinical improvement there was a coincident reduction of retention of bromsulphalein to grade 3, to grade 1, and finally to 0, and the van den Bergh reaction became indirect. Complete recovery ensued.

This patient had had syphilis and some enlargement of the liver for a number of years. The former had been adequately treated. The acute digestive symptoms were very suggestive of hepatic disease and functional tests confirmed the suspicion of its presence. Under treatment for hepatic disease, the woman recovered. There was no relapse in the serologic characteristics of the blood or spinal fluid in the course of this illness and the rate of recovery was more rapid than one would expect in a case of syphilitic hepatitis, judging from the amount of mercury administered. The illness was probably not due to latent toxic effects from previous therapeutic agents, for antisypilitic drugs had not been given in the preceding two years. Furthermore, no history of the use of other hepatotoxic drugs was obtainable and there was no evidence of other systemic diseases that could affect the liver. It is my opinion that the illness of this patient was an acute degenerative lesion of the liver, of unknown etiology, and particularly not necessarily attributable to the syphilis or its treatment.

Hepatic involvement may appear in the secondary or tertiary stages of acquired syphilis. Enlargement of the liver and jaundice are common manifestations in all forms of syphilis. Since arsphenamine² has been used in the treatment of syphilis, jaundice has been more frequently observed, especially in the secondary stage. A higher incidence of acute atrophy of the liver also has been noted. Although the hepatic disease, with

1. Weir, J. F.: The Diagnosis of Jaundice: Value of Clinical and Laboratory Data, *Am. J. Surg.* 15: 494-503 (March) 1932.

or without jaundice, in the presence of active syphilis untreated or in the course of being treated, is frequently and presumptively attributable either to the primary disease or to the agents used in its control, the possibility of intercurrent and unrelated conditions of chronic or acute nature must be considered. Only recently a case of syphilis under treatment was encountered in which jaundice developed. Careful inquiry was necessary to elicit a history of cholecystitis and a subacutely inflamed gallbladder containing stones subsequently was removed. A positive serologic test for syphilis in a case of hepatic disease does not necessarily mean that the condition of the liver is due to syphilis. Other evidence usually is necessary. Such evidence, however, often is not obtainable or may become available only at necropsy.

HEPATITIS WITHOUT JAUNDICE

Jaundice is the symptom which leads all others in calling attention to the presence of hepatic disease. In absence of this symptom the occurrence of an enlarged liver or spleen, ascites, pruritus and hematemesis also serve to direct attention to the liver. However, there are many cases of hepatic disease wherein none of these conditions are present. The condition, in such cases, may spring from various diseases or toxins but in many the etiology is unknown. Comfort and I² have reported cases of hepatic disturbance attributable to cinchophen wherein jaundice was absent. Numerous similar cases subsequently have been encountered. The use of hepatic functional tests has aided materially in their recognition and in the institution of protective measures. Likewise these tests, judiciously used in examination of the syphilitic patient who is under arsphenamine therapy, have disclosed development of hepatic injury in its earlier stages. The occurrence of hepatic involvement in fatal cases of pernicious vomiting of pregnancy long has been recognized but it remained for tests of hepatic function to demonstrate the common occurrence of various degrees of disturbances of the liver in the less severe cases. It is also known that fatal acute atrophy of the liver may occur without the development of jaundice. The changes in the liver in the presence of severe anemia have been emphasized by Rich.³ Recently, Snell and Comfort⁴ have described cases of presumably fatty degeneration of the liver without jaundice, associated with extreme atrophy of the pancreas. Involvement of the liver in cases of exophthalmic goiter has been described by numerous authors. The cases of Beaver and Pemberton⁵ were severe and the outcome was fatal. It is not so well recognized that minor degrees of hepatic disturbance may occur in milder cases of exophthalmic goiter, although Bartels⁶ has found frequent disturbances of the liver in such cases, using the hippuric acid test. At the clinic, however, we prefer to depend on the bromsulphalein test in those cases in which jaundice is absent.

A number of cases of hepatic disease without jaundice, unassociated with other diseases and of unknown etiology, have been encountered. Although these have

been discussed in detail elsewhere,⁷ I present one as illustrative of the group:

CASE 4.—A man aged 34 was seen repeatedly between 1932 and 1934 for duodenal ulcer and sinusitis. In March 1934 resection of the stomach was done with excellent results. The liver was grossly normal. In December 1936 the man returned because of periumbilical distress of two months' duration associated with insomnia, anorexia, marked nausea and loss of 10 pounds (4.5 Kg.). Physical examination revealed no abnormalities. Retention of bromsulphalein was graded 4. The van den Bergh reaction was direct; the concentration of serum bilirubin was 1.6 mg. per hundred cubic centimeters. On a high carbohydrate diet and daily intravenous administration of dextrose solution, the patient's condition gradually improved. Coincidentally, retention of bromsulphalein declined; it was graded 3, 2, and subsequently 1, in the two weeks following the patient's admission. Another four weeks elapsed before the patient fully recovered. Examination one year later showed him to be in good health.

The occurrence of anorexia, nausea, vomiting and epigastric distress brought the liver under suspicion. The absence of jaundice or hepatic enlargement necessitated the employment of hepatic functional tests for confirmatory evidence. The severity of the symptoms and the laboratory observations indicated a rather severe lesion of the liver. Improvement in the laboratory appearances coincided with the clinical improvement. Etiologically, evidence of any known exogenous or endogenous toxic agent could not be demonstrated and the case must be considered one in which the hepatic condition was of unknown origin. The normal condition of the liver at the previous exploration, and the course of the later illness, would seem to indicate that the acute hepatic injury underwent complete resolution.

In a few cases slight enlargement of the liver directed attention to the possibility that it had undergone pathologic change. In other cases, indefinite or extremely mild symptoms were present and the laboratory investigation was made in an effort to find an explanation for some of them. In further cases, symptoms were more severe and suggestive of hepatic disease and functional tests indicated hepatic changes. In the milder cases, definite, active therapy did not seem indicated. However, subsequent avoidance of hepatic toxins was counseled. In the more severe cases, more active therapy was needed. In these, the standard, high carbohydrate, diet supplemented by intravenous administration of dextrose solutions when necessary proved adequate. The pathologic changes were conjectural, material for biopsy was not available, and fortunately the need for necropsy did not arise. Presumably the changes were degenerative processes or some degree of necrosis of the hepatic cells. Prognosis also was uncertain. In cases in which there was some enlargement of the liver chronic changes probably were present; exacerbations probably were in progress at the time of our observations. Similar exacerbations may occur in the future. In other instances there is every reason to believe that the illness was acute, although of varying degree of severity, and that recovery was complete.

FUNCTIONAL TESTS

In the presence of jaundice the measurement of the concentration of bilirubin in the serum furnishes information of utmost importance. The highest levels (from 30 to 50 mg. per hundred cubic centimeters) are found in association with acute, severe, hepatogenous forms

7. Weir, J. F.: Atrophy and Necrosis of the Liver Without Jaundice, unpublished data.

of jaundice and cases of neoplastic biliary obstruction. In cases of *incomplete obstruction*, high readings (20 mg. or more per hundred cubic centimeters) indicate definite parenchymal involvement of the liver. Fluctuations in such cases are not as frequent as they are in the more common degrees of icterus from intermittent obstruction. However, after a considerable period slow decline may occur. This would indicate a tendency to partial recovery from the hepatic injury. The longer the high level is maintained, the more severe is the injury and the slower will be the decline of the concentration of serum bilirubin.

In the absence of jaundice, determination of the excretory function of the liver by the rate of excretion of various dyes yields most important information. In general, in these cases, the degree of retention of dye can be taken at its face value. Even slight retention of dye is significant. Retention occurs in a wide variety of primary hepatic diseases, in many of which high degrees of retention are indicative of an unfavorable prognosis. Hepatic involvement often can be demonstrated in a number of other conditions, such as exophthalmic goiter, toxemia of pregnancy, amyloidosis, poisoning from various hepatotoxic substances such as cinchophen and arsenic, many of the infectious diseases, and the infiltrations of malignant and leukemic processes. In other instances, such as in case 4, hepatic involvement may be demonstrable in the absence of associated diseases and clinical evidence of hepatic disease may be minimal. Lessening of the degree of retention usually parallels clinical improvement.

Hypoglycemia has been noted experimentally in hepatic injury from various toxins, and occasionally in a variety of clinical hepatic diseases. However, the glycogenic function seems well maintained as a rule, to the end. Other functions tend to fail first. For this reason, functional tests of carbohydrate metabolism have been disappointing in practice. The galactose tolerance test has had a greater vogue than others in clinical medicine. The test has been used to distinguish intrahepatic from obstructive jaundice, by obtaining positive results in the former, but we have not been able to confirm this use of the test. Thus, in our hands the test has been consistently negative in portal and biliary cirrhosis and positive in from 25 to 40 per cent of cases of obstructive jaundice.

In acute hepatic disease, such as yellow atrophy, the blood amino acid may be increased, the urea may be decreased and tyrosine may appear in the urine. The liver has been shown to be important in maintaining the normal level of serum proteins. Lowering of these has been noted frequently in experimental and clinical hepatic disorders, especially in instances in which edema or ascites was present. Reversal of the albumin-globulin ratio not infrequently is encountered. Lowering of the colloid osmotic pressure also may occur and, as Butt and Keys⁸ have shown, does not necessarily parallel lowering of the serum protein.

Fatty changes in the liver and alteration of the blood lipids occur in many experimental and clinical conditions. Extensive fatty changes have been noted to occur in depancreatized animals. Similar clinical instances of presumably fatty liver in cases of extensive chronic pancreatic disease have been noted. In obstructive jaundice, cholesterol and cholesterol esters in the

blood are frequently increased; in some instances of chronic obstruction these are extremely high and fail to return to normal even after relief of the obstruction, thus indicating permanent hepatic damage. In parenchymatous hepatic disease a marked decrease of cholesterol and cholesterol esters is noted at times. Cholesterol esters may entirely disappear from the blood in the more severe cases of this type and may be indicative of an unfavorable prognosis. Other disturbances of lipid metabolism include a lowered output of cholesterol in the bile and lipemia. Riegel, Ravdin and Rose⁹ have shown the prognostic import of low output of cholesterol in bile drained from the common duct. Occasionally we have encountered arterial lipemia in the terminal stages of chronic hepatitis and we encountered venous lipemia in a case of splenic anemia following splenectomy.

Of the tests of the detoxifying function of the liver, the one based on the ability of the liver to conjugate benzoic acid and aminoacetic acid to form hippuric acid has best stood the test of clinical evaluation. In a case without jaundice the results parallel closely those of the bromsulphalein test, while in a case in which jaundice is present they correspond, in a general way, to the degree of hepatic injury noted at operation or necropsy. In "surgical" types of icterus it has been found that values of less than 1.5 Gm. were associated with an unfavorable prognosis. In case 1 the low results indicated hepatic disease.

A study of the bile discharged from the drainage tube in surgical cases also offers valuable information of the functional capacity of the liver. Marked cholorrhea indicates an unfavorable course. Gray and McGowan¹⁰ have demonstrated the significance of lowering of the bile salt output. Amounts less than 100 to 200 mg. per hundred cubic centimeters of bile indicate extensive hepatic damage and, frequently, a fatal prognosis.

Because of the many functions of the liver, many tests of its function have been developed; and, while no one test gives complete or perhaps significant information on how the liver is functioning in a given instance, the use of several gives more accurate knowledge of its condition. Some tests are more applicable in some cases than in others. Positive results are particularly significant in demonstrating advanced changes. By the use of functional tests, progress is being made in the study of clinical cases and in knowledge of the pathologic physiology of the liver. Such studies may definitely incriminate the liver in various diseases wherein hepatic involvement may occur but is unsuspected. When such involvement of the liver has been demonstrated, the degree of alteration of the functional tests may be indicative of the extent of such involvement, its course and its prognosis.

SUMMARY AND CONCLUSIONS

In this discussion I have attempted to point out some forms of hepatitis not commonly recognized, namely (1) chronic hepatitis either masquerading as stone of the common duct or in association with calculous cholecystitis, and the acute and chronic degenerative hepatic lesions which may accompany stone of the common bile duct; (2) hepatitis occurring in the course of syphilis and its therapy; (3) hepatitis of several types without jaundice. In cases of the first group, diagnosis

often is uncertain until exploration is undertaken. However, the presence of unusual symptoms such as unexplained weakness, loss of weight, dyspnea and edema may arouse suspicion that the liver is of more importance than the cholecystic disease or the condition of the rest of the biliary tract in explaining the patient's illness. Hepatic and splenic enlargement are indicative of long-standing disease. Chronic jaundice and ascites are also important signs of extensive disorganization of the liver. Intense jaundice (high levels of serum bilirubin), especially in the absence of complete ductal obstruction, indicates acute hepatic damage. This may manifest itself in such a serious form as acute yellow atrophy. An attitude of constant suspicion of the possible presence of hepatitis is necessary in recognition of many of these states. Hepatic functional tests, particularly determination of the serum bilirubin, the galactose tolerance, the excretion of hippuric acid and the concentration of cholesterol and protein in the blood in the presence of jaundice and determination of the rate of excretion of bromsulphalein in the case without jaundice, offer much assistance. Although these tests may present positive evidence, the disposal of such cases will rest largely on clinical grounds. Knowledge of the value and interpretation of such tests has not progressed to the stage of infallibility and, on the basis of their results, patients cannot justly be denied their only chance of cure or even of palliation. However, positive tests give better evaluation of the risk and indicate that adequate time should be taken for thorough preoperative preparation.

Acute hepatitis in association with syphilis and its treatment usually is readily recognized and often is attributable either to the primary disease or to its therapy. However, the possibility of independent lesions cannot be ignored and difficulty may be encountered in the absence of jaundice. Laboratory procedures may aid in confirmation of suspicions.

A variety of causes may give rise to disorders of the liver without jaundice. Many such cases and their etiologic factors are readily recognized, but there are unusual cases, unassociated with other diseases and of unknown etiology. The bromsulphalein test for hepatic function has been particularly valuable in recognition of these cases and as an indication of improvement. Anorexia, epigastric distress, nausea and, at times, vomiting have been prominent symptoms and, unless otherwise explained, such a syndrome should direct attention to the liver.

ABSTRACT OF DISCUSSION

DR. DWIGHT L. WILBUR, San Francisco: This paper calls attention to the value of certain tests of hepatic function when they are viewed in the light of clinical observations. The symptoms of hepatitis with the exception of jaundice and of an enlarged and tender liver are nonspecific, for one may observe upper abdominal colics, nausea and vomiting, pruritus, hematemesis, anorexia, epigastric distress and loss of weight and strength and discover an enlarged spleen, ascites or melanoderma in the absence of disease of the liver or biliary tract. If these symptoms are present or if such observations are made one may suspect the presence of hepatic disease, and the use of certain tests of hepatic function may aid in substantiating or establishing the diagnosis. One should not gain the impression that tests are required if accurate determination and interpretations and degree of hepatic derangement. In the first place considerable familiarity and experience with the technic of some of the tests is required if accurate determination and interpretations are to be made. In the second place clinicians with much experience in the use of these tests will recall instances in

which certain of them yielded results within normal limits in cases in which there was marked hepatic disease. For many clinicians the value of hepatic function tests lies principally in the fact that they establish a measure of the degree of hepatic damage in a case in which hepatic involvement is suspected clinically and that thereby is established a base line by which the preoperative or postoperative course and progress of hepatic function and disease may be more closely followed. For those who do not have access to a laboratory in which some of the more difficult tests for hepatic function can be carried out, observations of the intensity of the jaundice, of its duration, of its course (particularly whether it is fluctuating or constant) and observation (by means of the duodenal tube) of the presence of or absence of a flow of bile into the intestine will prove useful. Indeed the three most useful facts to be used in the differential diagnosis of patients with jaundice are the occurrence or absence of pain, the presence or absence of a flow of bile into the duodenum, and the degree and course of the jaundice. I am interested to know Dr. Weir's opinion of the value of determinations of total cholesterol and cholesterol esters of the blood, of the Takata-Ara test and of the phosphatase content of the blood as measures of hepatic function.

DR. SIDNEY A. PORTIS, Chicago: Many gastro-enterologists but too few clinicians realize the role of the liver in the metabolism of the body. We have just heard a good discussion of liver function, and yet all we know at present is that dextrose will help liver diseases. It seems that practically all the functions of the liver are dependent on the glycogenic content of the liver cell. When the liver is damaged it takes a higher concentration of sugar in the blood to reach the liver cell because the threshold in the liver is raised. One should necessarily question then whether or not there can be sufficient absorption of dextrose from the gastrointestinal tract in amounts that would be beneficial to a damaged liver. It would seem more logical to give dextrose intravenously so that the concentration of sugar in the blood reaching the liver at any one time would be sufficient to overcome the raised liver threshold for its utilization. Many physicians do not appreciate the so-called subhepatic states in which patients complain of lethargy, weakness and swelling. These are probably associated with hypoglycemic manifestations, which are dependent on the glycogenic function of the liver. I have been giving these patients 50 cc. of 50 per cent dextrose solution daily without insulin. I use insulin only when there is evidence of a diabetic component to the clinical picture. Some of the most marvelous results of intravenous dextrose therapy may be seen at times in cases of so-called atrophic cirrhosis of the liver. If the liver is not too badly damaged and beyond any repair, one may frequently see, after the daily intravenous injection of dextrose, a gradual but definite improvement in the clinical picture. Many of these patients do not have to be given paracentesis. Frequently the hemorrhages from the esophageal varices subside, and those patients who were relegated to the "junk heap" in the past have been able to regain their near normal status, gain in weight and for the most part become very comfortable.

DR. EDGAR WAYBURN, San Francisco: I have seen several cases of cirrhosis of the liver in which it was possible to make the diagnosis before jaundice developed. Three years ago I had the opportunity to observe one of these cases pathologically. In this case there was an acute inflammatory reaction and necrosis of liver cells in irregular zones having no constant relationship to the liver lobules. A similar type of reaction occurs in hepatic cirrhosis. In this case, however, there was a barely detectable amount of fibrosis. I tried without success to find similar cases in the literature. I believe that the signs which may be of value in such cases include nausea, vomiting, epigastric and right upper quadrant discomfort, weakness, a large and often tender liver, and impaired liver function, as Dr. Weir has pointed out. With regard to the differential diagnosis of gallbladder disease and cirrhosis, with Dr. Cherry at the San Francisco Hospital I have now used the Takata reaction in a series of almost 1,500 cases and in a number of instances have found that it was a very valuable laboratory aid in the differentiation of these two diseases. It is a test which in our series has been positive in 90 per cent of cases of cirrhosis of the liver and uniformly negative in gallbladder disease.

DR. JAMES F. WEIR, Rochester, Minn.: In reply to Dr. Wilbur's questions concerning the value of cholesterol and cholesterol esters and the phosphatase and Takata-Ara tests, it would take too much time to attempt an adequate answer. My experience has been similar to that of the Mount Sinai group with regard to the cholesterol and cholesterol esters. I have discontinued using the Takata-Ara test. The phosphatase has been helpful in some cases but there have been many exceptions. Dr. Portis seemed favorable impressed with the results of treatment in some of these advanced cases of cirrhosis or other hepatic disease. I think this is justifiable in certain cases. Judging from the wrecks that one sees, certain of them definitely can be rehabilitated. As these occur infrequently, however, one becomes discouraged at the bad results one gets in cirrhosis as a group. In closing, I want to emphasize in particular the last group of patients, with acute symptoms in the absence of jaundice, who have functional disturbances and usually recover.

COCCIDIOIDOMYCOSIS

THE PRELIMINARY ACUTE INFECTION WITH FUNGUS COCCIDIOIDES

ERNEST C. DICKSON, M.D.

SAN FRANCISCO

Since coccidioidal granuloma has been found to be of considerable frequency in California, particularly in the San Joaquin Valley,¹ and since it has been found that not only man but cattle and sheep may acquire the disease,² there has been much interest in how infection with the fungus *coccidioides* may be acquired. It has been shown that occasionally infection occurs first at the site of a break in the skin such as a puncture of a cactus spine³ or an abrasion from picking walnuts,⁴ but such a traumatic history has rarely been obtained. Clinical experience has shown that there is no indication of man to man or animal to man infection, and study of other possible methods of infection, including insect bite, have failed to show how the disease is transmitted. A number of clinicians have long suspected that the infection may follow inhalation of the infecting organism, but this has necessitated their disregarding the parasite as it occurs within the animal body, the endosporulating spherules, and has made it necessary to consider whether some element of the vegetative phase of the fungous growth might be the infecting agent.

Beginning with Dr. Ophüls,⁵ a few investigators, including Wolbach,⁶ MacNeal and Taylor⁷ and Ahlfeldt,⁸ have worked with *coccidioides* fungus, and all have recognized that the method of reproduction in the vegetative phase is by *chlamydospores*, organisms which usually have not been studied by clinicians because the clinician sees only the patient, and the endosporulating spherules, the cycle of reproduction within the tissues of the patient, are the only reproductive elements met in the parasitic phase of *coccidioides* activity. It has

seemed possible to some investigators that the *chlamydospores* of the vegetative phase might be the infecting organism which can be inhaled. In 1929 Ophüls⁵ while discussing the case report of Pulford and Larson⁹

All evidence so far gathered seems to point to respiratory involvement with primary localization of the virus in lung. . . . It is probably the spores of the fungus grow that become mixed with dust and are then inhaled into lungs. The finding of the disease in animals such as cats and sheep does not seem to me to suggest that the infection from animals to human beings. It is much more likely that the animals contract the disease much in the same way as human beings do in the infected region.

Proof that the inhalation of *chlamydospores* may cause *coccidioides* infection was established by an accident in our laboratory.¹⁰ A young man who was commencing work with *coccidioides* fungus inadvertently opened an old petri dish culture which he proposed to use. When the cover glass of the petri dish was removed he noted a fine cloud arise from the old culture. Nine days later he became ill with a symptom complex which has been found to be common in the San Joaquin Valley, Calif., the region in which approximately per cent of the known cases of coccidioidal granuloma in the United States have originated. Like the great majority of patients in the San Joaquin Valley, this young man recovered without complications, and he is now apparently well, nine years later. Shortly after this case, another young man, from near Bakersfield in the San Joaquin Valley, was under the care also of Dr. H. Pierson, suffering from a similar illness. The main difference between the two cases was that there was an outbreak of *erythema nodosum* in the first case but not in the second. In both cases cultures of sputum gave a growth of fungus *coccidioides* which was proven virulent by guinea pig inoculation. Like the first patient the second young man recovered promptly from this acute illness.

It has been found that a symptom complex like that of the first of these patients is common in the San Joaquin Valley; so common, in fact, that it is popularly known as "valley fever" or "desert fever." Persons of all ages and of either sex may be affected; they are usually ill from three to six weeks, and the most of them recover without having had any complications. Many apparently are not sufficiently ill in the beginning to call for medical aid; as a matter of fact, it is often *erythema nodosum* which brings them to a physician. In a questionnaire sent to the practicing physicians in the San Joaquin Valley, seventy-five physicians report that they had seen 354 patients with valley fever *erythema nodosum* between Jan. 1, 1936, and May 1937, of whom 353 had recovered without complications and one had died of coccidioidal meningitis.

At the onset of acute illness the patient usually describes it as a bad cold or "flu." He complains of feeling bad, with headache and often general aches and pains. Sometimes the aches and pains are particularly severe about the chest, and the patient complains of pleurisy; a number of such patients have had their chest strapped with adhesive tape. At times there are intermittent gastrointestinal disturbances. Frequently there is a mild sore throat which is called tonsillitis. Occasionally there is some conjunctivitis with bulbar hyperemia, but rarely are phlyctenulae seen. Sometimes there is

rapid loss of as much as 15 or 20 pounds (7 or 9 Kg.) in weight. Fever may begin at the onset or four or five days later. Not infrequently the temperature is no higher than 100 F., but sometimes, when there are signs of severe bronchitis or bronchopneumonia, it may be 104 or even 105 F. Occasionally a patient has an early chill and he may have sweating, but the incidence of chills and sweating is not constant.

There is early bronchitis, sometimes with unproductive cough, but varying amounts of mucopurulent sputum are common. Sometimes the duration of cough with sputum is very short but at other times the duration of the cough is longer, and the amount of sputum may be large and it may be streaked with blood. Often the patient feels better after a few days and thinks he is getting well, but in from eight to fifteen days after the onset erythematous nodules develop in the skin; these are popularly described as "the bumps." They are typically those of erythema nodosum on the shins but when they occur elsewhere are sometimes described as erythema multiforme. It is only after the occurrence of "the bumps" that the disease is known as valley fever or desert fever.

The nodules of erythema nodosum usually appear primarily on the shins, where they are most numerous. They may occur also on the thighs, buttocks, arms, upper part of the chest and scalp. They do not fluctuate or suppurate but may be fiery red and very tender or painful. It is often the pain of the erythema nodosum which brings the patient to a physician. Within from forty-eight to seventy-two hours the nodules begin to change from fiery red to purplish and to fade. They have usually disappeared in from four to five days except for a brownish pigmentation of the skin, which may persist for several weeks after the tenderness and swelling have disappeared. Occasionally, but rarely, there are recurring attacks of erythema nodosum during a single illness.

If roentgenograms of the chest are taken during the acute attack, dense shadows will usually be found in the hilar regions, indicating enlargement of the hilar glands. Radiating from the hilar region and more widely distributed through the lung area are densities indicating parenchymatous involvement in various parts of the lung; these may occur in all the lobes. A roentgen diagnosis of tuberculosis is often made on the first examination, but as time goes on the areas of increased density gradually clear up until, after a few weeks, the lungs may appear entirely clear. Not infrequently the roentgenologist states the conclusion that the condition could not have been tuberculosis because the lungs cleared so promptly. Occasionally a patient with such pulmonary shadows has been sent to a sanatorium for tuberculosis when it was impossible to prove tuberculosis by recovering acid-fast bacilli or by tuberculin tests.

When sputum from a patient with valley fever is examined it is usually impossible to find acid-fast bacilli, although patients have been known to have both coccidioides infection and tuberculosis. Not infrequently, however, all that is found is the spherules of the coccidioides type with culture of fungus coccidioides, and coccidioidal granuloma in injected guinea pigs. Seventy-two of 112 specimens of sputum which were sent to our laboratory from the San Joaquin Valley have proved positive for coccidioides infection. In only four were tubercle bacilli found. It is not yet known how early in the disease the coccidioides fungus may

be found in the sputum or how long it may persist, although it is known that it may disappear before the output of sputum is discontinued. It should be remembered that, as in tuberculosis, the infecting organism may be recovered by washing the stomach of a child who is too young to raise sputum. We have studied several such cases,¹¹ and the typical spherules were seen in the mucopurulent sputum recovered by lavage, cultures showed growth of fungus coccidioides and the organism was proved virulent by guinea pig inoculation.

Examination of the urine shows nothing different than is usual in the case of febrile conditions. The leukocyte count varies from about normal to 15,000 but often, associated with the erythema nodosum, there may be eosinophilia. The highest eosinophil count we have seen was that of a patient whose leukocytes varied from 8,000 to 13,500; there were 4 per cent eosinophils on admission, 16 per cent on the eighth day of illness and 4 per cent again on the eleventh day. We have had opportunity of making sedimentation tests on three patients and found values of 31 mm., 32 mm. and 45 mm., respectively, in sixty minutes.

The use of the coccidioidin cutaneous test in cases of valley fever has been most helpful in correlating the diagnosis with coccidioides infection. It has been found that the reaction in cases of valley fever is much more violent than in cases of coccidioidal granuloma. As a matter of fact, the size of the dose for intradermal injection was stated by Jacobson¹² to be 0.3 cc. of the undiluted filtrate, which he prepared for diagnosis of coccidioidal granuloma, but such a large dose has proved entirely too strong for valley fever. It may cause immense edema and necrosis of the skin in cases of acute involvement. We have found that 0.1 cc. of a 1 to 1,000 dilution of coccidioidin which we have prepared is adequate and produces well marked reactions, sometimes with vesicle formation in cases of primary infection. At least 0.1 cc. of a 1 to 10 dilution of this coccidioidin is necessary for coccidioidal granuloma. This corresponds to the experience of Wallgren¹³ with tuberculin in the case of primary tuberculosis. He reported that among children with erythema nodosum accompanying primary tuberculosis the sensitivity to tuberculin may be so high as to cause a reaction to 0.000001 mg., whereas only three of 321 tuberculous children without erythema nodosum were sensitive to 0.001 mg.

However, there are also cases of primary coccidioides infection which differ only in the fact that there is no erythema nodosum, and they are therefore not considered cases of valley fever. It has been found that in these cases too there may be fungus coccidioides in the sputum, and there may be prompt recovery from the acute illness. The diagnosis may be bronchopneumonia or influenza, and, as with valley fever, the condition may go on to typical coccidioidal granuloma. We have seen two such cases in which recovery occurred and have records of several in which coccidioidal granuloma developed, as well as records of several in which coccidioidal granuloma developed after erythema nodosum. At the present time there is no knowledge as to how frequently the acute infection may occur with or without erythema nodosum or as to whether either type is apt to be followed by coccidioidal granuloma more often than the other.

13. Wallgren, Arvid: *Lancet* 1: 359 (Feb. 12) 1938.

It is therefore definitely established that infection with coccidioides fungus is caused by the chlamydo-spores of the vegetative phase of the fungus, which in some way gain access to the tissues. There seems to be no doubt that the chlamydo-spores are carried through the air, presumably associated with dust. When primary cutaneous lesions follow trauma of the skin, such as a prick of the skin by a cactus spine or an abrasion of the skin caused by picking walnuts, undoubtedly the chlamydo-spores are associated with the dust on the offending objects. In general, however, primary coccidioides infection seems to be acquired by inhalation of the chlamydo-spores, and the development of the primary lesions is in the lungs or the regional lymph glands. Thus can the occurrence of coccidioides lesions in animals in the endemic areas as well as in man be rationally explained. The development of the later coccidioid granuloma is undoubtedly secondary and is caused by migration of the virus to different parts of the body from the primary foci in the lungs or peribronchial lymph glands, presumably by the blood stream.

It follows therefore that infection with coccidioides fungus may be manifested in at least two ways: by a primary acute infection of the respiratory tract, often accompanied by erythema nodosum, from which the great majority of patients recover without complications, and by a later more or less chronic granulomatous disease, known as coccidioid granuloma, which may be very disabling and which has a case mortality rate of approximately 50 per cent. It is therefore necessary to have a name for coccidioides infection to include both types of illness. In a previous report¹¹ I suggested the term coccidioidomycosis, which may be classified as primary for the acute initial infection and progressive or secondary for the stage of coccidioid granuloma. The latter classification may be subdivided to indicate the regional distribution of the lesions if desired; for instance, of the skin, bone, meninges, lungs and so on.

SUMMARY

The preliminary illness caused by infection with fungus coccidioides has been recognized.

The disease is caused by inhalation of the chlamydo-spores, which are formed in the vegetative phase of growth of the fungus.

It is a form of infection of the respiratory tract, in many cases accompanied by erythema nodosum, and the great majority of patients recover promptly without complications.

The incidence of erythema nodosum is very high but not constant. When this condition occurs the disease is known in the San Joaquin Valley as "valley fever" or "desert fever."

The acute illness, whether or not there is erythema nodosum, may progress to coccidioid granuloma.

ABSTRACT OF DISCUSSION

DR. K. F. MEYER, San Francisco: I call this presentation the renaissance period of coccidioidomycosis. All have been interested in this disease for many years; from an epidemiologic standpoint the available story didn't fit. How could a disease have 98 or 99 per cent mortality? Anybody who thinks biologically was aware that doubtless coccidioid granuloma was merely the end result of a disease which masqueraded under an entirely different picture. Dr. Dickson has opened the door to let us look into this exceedingly complex problem. Since Coccidiomyces is not transmitted from host to host and does not behave as a true parasite along infection chains, one has to ask: Is it a pathogenic saprophyte and does this patho-

genic saprophyte acquire later parasitic properties? If so, what types of poison does it produce and what is the pathogenesis? I could mention an unlimited number of questions which doubtless Dr. Dickson and his associates are going to answer, but a few I should like to point out because we are here in a public health section. In the first place, the infection in California is aerogenic; the lung is the portal of entry. It therefore can occur only in regions where the atmospheric conditions favor the dissemination of the chlamydo-spores in the dust. It is interesting that by contrast the paracoccidioidomycosis of Brazil, recognized many years ago and carefully studied by Almeida, is apparently not aerogenic. In a tropical climate dust infections are infrequent. The North American coccidioidomycosis apparently is primarily a pulmonary infection with secondary distribution along the hematogenic route, while the South American type is a local process with primary distribution in the buccal cavity—tonsillar invasion and infection of the tongue and intestine. Of the total number of cases, over 280, that came to autopsy in Brazil, only about 15 per cent showed pulmonary lesions, which to all intents and purposes were decidedly secondary. I wish to stress these interesting biologic differences. Next I should like to call attention to the possibility which is reasonable to suspect, that, since we are dealing with a saprophytic fungus, we might find a great variety of Coccidiomyces, varieties from the standpoint of biology and their behavior toward the host. Just as in the field of sporotrichosis at least three varieties have been recognized and in the field of toxicogenic saprophytes, such as *botulinus*, five types have thus far been reached, A, B, C, D and E, I shouldn't be surprised if the rest of the alphabet would be fulfilled if every section of the world should be searched. These considerations raise the question Should the antigens which are to be used in the allergic tests, like the coccidioidin, be made from one strain or should a polyvalent preparation be used? We should not perhaps let our interest be entirely directed in analyzing the parasite, but we must study the factors which influence the host.

DR. KENNETH H. ABBOTT, Ontario, Calif.: I have a word to add in expressing our compliments to Dr. Dickson for the work presented here. Those of us interested in neurology occasionally see one particular type of this disease that is not generally recognized. I refer to the "primary coccidioid meningitis." Although it is at times possible to find in the history and the autopsy a previous infection, more often none is evident and no primary focus is found at autopsy. Most of these patients come to the neurologist because of just headaches, of symptoms of brain tumor or of meningitis and finally die after from three months to a year without a correct diagnosis unless the organisms in the spinal fluid are found or, as in one of our cases, a suboccipital exploratory craniotomy is done to make the diagnosis. We have been studying this type of occult coccidioid infection at the Cajal Laboratory of Neuropathology (Los Angeles General Hospital) and have corroborated Dr. Dickson's finding of eosinophilia in the blood and have also found in one instance a 15 per cent eosinophilia in the spinal fluid. I would mention one other diagnostic point: in cases of unknown type of meningitis, the skull should be roentgenographed. If small, punched-out areas are found, one should beware. It may be coccidioides. We have found that to be so in several instances.

DR. ERNEST C. DICKSON, San Francisco: In reply to the question of Dr. Abbott, I have been attempting to learn something about the incidence of the acute symptoms in the cases of coccidioid granuloma which have recently been reported. Of course, in trying to get the early history of patients who died and came to autopsy some time ago, little success has been achieved as a rule. However, among the cases that came to autopsy during the past year it was found that thirteen had initial symptoms of what could be called "flu," three diagnosed as pneumonia and three with indefinite histories from which no tentative diagnosis could be made. Of the seventeen patients who died, six had coccidioid meningitis, some of which corresponded with an acute illness in which an early diagnosis of meningitis had been made although, in some, diagnosis of coccidioid infection was not recognized before the patient was out of bed because of the primary illness. The fact that no primary lesions were diagnosed at autopsy does

not seem to me to indicate that there need be any other suspected method of causing the lesions in the meninges than is known, to occur so often. As Dr. Meyer stated, there are many questions which he would like to have settled. I have thought of many but undoubtedly not all of them. At present a rather satisfactory field investigation is in progress in the San Joaquin Valley that is resulting better than might have been expected. However, there remains much to learn about this disease, considered particularly from the standpoint of how it begins rather than from the standpoint of what eventually happens.

DECOMPRESSION OF THE SMALL INTESTINE IN THE TREATMENT OF INTESTINAL OBSTRUCTION

CHARLES G. JOHNSTON, M.D.

GROVER CLEVELAND PENBERTHY, M.D.

R. J. NOER, M.D.

AND

J. C. KENNING, M.D.

DETROIT

The role of distention as an important factor in the initiation of conditions which lead to a fatal outcome of intestinal obstruction has been well demonstrated within the last few years. The work of Ward¹ and of Wangenstein^{1a} with respect to the beneficial effects of gastric or duodenal suction is based largely on the proposition that with relief of distention not only does the patient become more comfortable but in many cases the release of tension above the obstruction permits passage of the intestinal contents through the narrowed lumen of the bowel. The role of distention in the initiation of vomiting, the common precursor of loss of fluid and salt in cases of intestinal obstruction, has been well studied by Herrin and Meek.² These authors pointed out that it is possible to produce the symptoms and sequelae of intestinal obstruction in animals by distention even though obstruction is not present.

Beneficial effects from enterostomy in cases of intestinal obstruction likewise attest the efficacy of decompression of the distended bowel in the control of intestinal obstruction. Enterostomy when it decompresses the bowel directly above the site of obstruction is a surer method than is gastric or duodenal suction, but the operation entailed frequently negates this advantage.

With encouragement from the assistance offered by gastric or duodenal suction after the method of Wangenstein in the treatment of intestinal obstruction and the knowledge of the technic and possibilities of intubation of the small intestine, Dr. William Osler Abbott and one of us prepared to pass a tube into the small intestine of a patient with intestinal obstruction who had refused operation. The tube passed with greater ease than we had anticipated, and decompression of the distended intestine was effected.

From the Departments of Surgery and Roentgenology, Wayne University College of Medicine, and the Detroit Receiving Hospital. Aided by a grant from the Committee on Scientific Research of the American Medical Association.

Read before the Section on Surgery, General and Abdominal, at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

2. Herrin, R. C., and Meek, W. J.: *Distention as a Factor in Intestinal Obstruction*, *Arch. Int. Med.* 51:152 (Jan.) 1933.

A certain amount of rationalization was necessary to enable us to proceed with the treatment of intestinal obstruction by the use of intestinal intubation. The question of the efficacy of the method was of no great concern, since we had clearly demonstrated that even when a patient was vomiting the contents of the small intestine the tube would pass down the small intestine to the cecum and the contents of the small intestine removed from just above the point of obstruction, the site of election for an effective enterostomy. This procedure in effect was tantamount to an enterostomy without the trauma of an operation.

However glowing the possibilities seemed, other factors gave us concern. The likelihood that the period consumed in passing the tube might be valuable time lost to the patient appeared important. With the tube placed in the stomach or duodenum, suction could be applied and would then be as effective as the form of early preoperative care to which we had become accustomed since the popularization of suction drainage by Wangenstein and Paine.³ This treatment should be instituted while fluids are administered even though early operation is contemplated. The further passage of the tube might require hours, but if the patient was watched carefully for the development of untoward signs, this did not need to be of any great moment in the majority of instances. Subsequent experience has strengthened our point of view in this regard. Occasionally passage of the tube to the point of obstruction has required more time than expected, but we have not felt that this has been a deterring factor.

We recognized early the possible dangers of intubation of the small intestine in cases of strangulation. Obviously, strangulated obstruction requires early surgical intervention and even a few hours' delay may be costly. The problem here rests with the possibility of correctly diagnosing strangulated obstruction. That this can be done with some degree of accuracy is evident from the fact that, during the past year and a half, of twelve patients with strangulated obstruction who were treated in our service at City of Detroit Receiving Hospital all were operated on without delay.⁴ The errors in diagnosis were made in occasionally considering that nonstrangulated obstructions were strangulated.

Some comfort, in addition, was given to us by the statistics of McIver,⁵ which showed that in the type of case in which strangulation usually occurred (exclusive of external hernia, the diagnosis of which is usually obvious) the incidence was but 11 per cent. The conditions are volvulus, internal hernia and intussusception. Occlusion of a mesenteric artery or vein has a high mortality whether or not operation is performed, and we have come to feel that, with the possibility of better revascularization in a collapsed bowel, the patient's chances are a bit better if the intestine is kept decompressed. Since the incidence of true strangulation is low, the increase in total mortality should not be great even if the condition was not recognizable and operation was therefore delayed.

Support for the point of view which permitted us to proceed with this problem has been afforded in the cases we are now prepared to report. It is true that the number of patients with intestinal obstruction

treated by intestinal intubation has been small and the experience therefore not truly conclusive. However, the series is large enough and the result striking enough to determine that the method is not likely to cause an increase in the death rate. The results rather indicate that a definite decrease in mortality should result.

The method of intestinal intubation has been described adequately elsewhere.⁶ It consists of the passage through the nose of a 16 to 18 gage tube from 10 to 12 feet in length on the end of which is attached

of the balloon. Failure to decompress ahead of the balloon will result in stoppage of the forward progress of the tube.

The cases which we are reporting are cases of acute intestinal obstruction or cases in which paralytic ileus associated with other conditions threatened the life of the patient. In addition, we have used intubation prophylactically in a large number of cases in which ileus was expected to result as well as in cases in which distention was of minor consequence in relation to a

Fatal Cases

| Patient | Cause of Death | Decompression | Comment |
|--|---|----------------------------------|--|
| Patients Who Died as a Result of Their Obstruction | | | |
| L. V., aged 81 | Richter's hernia, perforation of ileum, peritonitis | Unsuccessful | Patient had diaphragmatic hernia, unrecognized Richter's hernia; tube never entered abdominal portion of stomach |
| M. T., aged 69 | Perforation of ileum, peritonitis | 1. Successful 2. Unsuccessful | Patient emaciated; obstruction at terminal ileum completely decompressed; patient fed and appeared ready for operation after 26 days of intubation; operation deferred to allow gain in strength; after 4 days, obstruction reappeared and intestine perforated before tube could be passed; fine adhesive band found across terminal ileum, with pinpoint perforation |
| C. M., aged 51 | Ileus involving entire gastrointestinal tract | Unsuccessful | Seen 6 hours before death; symptoms of 1 week's duration; 4 liters of fluid with much gas removed from stomach; intravenous injection of fluids started but patient died suddenly before second thousand cubic centimeters was introduced |
| N. G., aged 75 | Intestinal obstruction | Successful (late) | Refused all treatment; home on release; returned 5 days later; wanted to die and refused intubation; successful intubation done when patient was moribund |
| H. B., aged 20 | Intestinal obstruction | Successful | Refused intubation; operation, and adhesive band released; in good shape for 8 days; crampy pains recurred and relieved by intubation; sudden return of abdominal pain 12 hours before death; x-ray examination showed complete decompression; autopsy refused |
| Patients Who Died from Causes Other Than Obstruction, with Distention Playing a Part in the Outcome | | | |
| J. W., aged 33 | Septicemia following gunshot wound, right arm, pericarditis, empyema, peritonitis, multiple localized abscesses | Unsuccessful | Impossible to turn on right side; tube would not enter duodenum; enterostomy performed |
| J. O., aged 52 | Nephritis, diabetes mellitus, uremia | Unsuccessful | Patient had old fistula following enterostomy; tube thought not to offer much advantage, inserted but irritable patient removed it; blood sugar 390, urea 115, carbon dioxide 33; chlorides always within normal limits |
| A. O., aged 77 | Pylonephritis, retroperitoneal abscess | Successful | Ten days' distention and obstipation; gastric suction 3 days before patient was seen by us; patient died of infection, but long continued distention probably played a part in her death |
| R. J., aged 26 | Pylonephritis, uremia | Successful | Patient's obstruction overcome at this and two previous admissions; previous admission for pylonephritis; abdomen flat one week before death; chlorides within normal limits; blood urea 118 |
| Patients Who Died from Causes Other Than Obstruction, with Distention Playing No part in the Outcome | | | |
| J. M., aged 48 | Chronic granuloma of the retroperitoneal tissue and mesenteric lymph glands, evisceration, cachexia | Successful | Long tube used to keep distention down after evisceration |
| E. R., aged 39 | Cardiovascular renal disease, lobar pneumonia | Successful | Distention completely relieved; tube out 1 week before death without return of troublesome distention |
| R. Z., aged 44 | Encephalomalacia of left temporal lobe, cirrhosis of liver, chronic alcoholism | Successful | Ascites massive; intestine kept decompressed with tube |
| A. D., aged 60 | Bronchopneumonia | Successful | Distention of small bowel controlled with long tube; large bowel controlled partially with enemas |
| R. L., aged 44 | Ruptured appendix, subhepatic abscess, retroperitoneal cellulitis (right side) | Successful | Intestine kept successfully decompressed; patient died of infection |

an inflatable balloon. When the tube is well into the duodenum the balloon is partially inflated, and peristalsis pulls the tube and balloon past the ligament of Treitz. At this point the balloon is fully inflated, to a capacity of from 40 to 60 cc., so that the intestine can act on a larger volume. The reason for not inflating the balloon fully in the duodenum is twofold: (1) If inflated fully the balloon and tip occasionally pull back into the stomach and (2) if too fully inflated the balloon passes with difficulty past the fixed portion of the upper part of the intestine, the lower part of the duodenum. As the tube progresses down the intestinal tract, fluid and gas are aspirated from the dilated intestine ahead

lethal outcome. These two types of cases we will not consider in this report, nor do our statistics include cases in which intubation was not used but operation was performed because of strangulation or suspected strangulation, unless alarming distention necessitated postoperative intubation.

Of the fifty-four patients, fourteen died. Of these, five died as a direct result of obstruction. The remaining nine patients died of other causes, and as a rule intubation was carried out to control distention associated with the conditions which caused death. In four cases distention appeared to be an associated factor in causing the death, and in five it was difficult to ascribe to the distention any part in the patient's death. The accompanying table contains the details of the fourteen fatal cases.

COMMENT

Intestinal intubation as an adjunct to the treatment of intestinal obstruction has proved successful in our hands in a small series of cases. That alone it cannot be depended on is obvious from the fact that intestinal obstruction is protean in its manifestations and causes. Each case must be individualized and the obstruction treated as to its specific requirements. Intubation does not exclude operative means of handling obstruction but rather facilitates any operative procedure which may be necessary.

The advantages of the method in properly selected cases are as follows:

1. It carries the patient past the period when operation is most dangerous.

2. It prepares the patient for operation by control of distention, thus making operation less traumatic for the patient and easier for the surgeon.

3. It affords a means of localizing the site of obstruction and frequently indicates its nature.

4. It permits oral feeding of the patient during a period when food and fluid are so essential and frequently has permitted us to improve the patient's nutritional state during the period of treatment.

5. It releases the tension above the site of obstruction and frequently reestablishes the normal passage of intestinal contents, thus permitting the patient to be operated on in the interval stage if advisable.

6. In the treatment of paralytic ileus this is the only method we know of which can uniformly be depended on to relieve the distention of the small bowel, which is not uncommonly fatal.

The disadvantages of the method are as follows:

1. It necessitates careful selection and evaluation of cases. It is not suitable for treatment of strangulated types of obstruction.

2. It requires hard work on the part of the surgeon and his associates. Passage of the tube and attention to details with regard to the patient and the equipment require continued attention.

3. It is not suitable for obstruction of the large bowel, since, despite the fact that the tube frequently traverses the entire intestinal tract, it cannot be depended on to reach the large bowel quickly enough to be of value.

In our series of fifty-four patients treated by intubation of the small intestine, fourteen patients died, a mortality of 25.6 per cent. Of these, five, or 9.3 per cent, died as a result of intestinal obstruction. In the remaining nine who died, intestinal intubation was carried out to relieve distention associated with other conditions which caused the death. In a larger series of cases we have intubated the small intestine for relief of distention or to prevent the development of distention, but we have not included these cases in our series. Our reason for excluding them is that the distention was not severe enough to have caused death or, in cases in which intubation was prophylactic, that we could not be certain that severe distention would have resulted without the tube.

This series does not include cases in which treatment was solely by operative means. The number of cases presented is small, and conclusions regarding mortality are difficult. The data do, however, indicate that intubation of the small intestine in selected cases has a definite place in the care of patients suffering from intestinal obstruction.

1512 St. Antoine Street.

ABSTRACT OF DISCUSSION

DR. DWIGHT L. WILBUR, San Francisco: The double and multilumen tube has proved to be of great value in the study of the physiology of the small intestine. It has given more information with regard to the function of the small intestine than has any other instrument. Because of the ease with which it may usually be passed into the small intestine it is natural that its use should have been extended from physiologic studies to those of diagnosis and treatment of diseases of the small intestine. Since decompression of a hollow viscus above an area of obstruction is one of the cardinal principles of surgical treatment of such diseases, the double lumen tube should be of great value in the treatment of intestinal obstruction. Dr. Penberthy and his associates have demonstrated that this is the case. There are dangers in the use of this method of treatment, as the authors have pointed out, and I should like to emphasize two of them. The first is that when suction is applied and the intestinal contents are drained for any period the situation is comparable to that in which an enterostomy opening is present. Under such circumstances considerable care must be exercised to maintain an adequate balance of fluid and chloride. It is probably not wise to maintain constant suction over too long a period. There is danger also in the treatment of patients who have strangulation of the small bowel, and the possibility that strangulation exists will probably constitute the greatest limitation of this particular method of treatment of intestinal obstruction. The principal therapeutic uses of the tube probably will be in the treatment of obstruction of the small intestine which is mechanical in nature, in the treatment of paralytic ileus and in the preoperative treatment of patients with obstruction who have marked abdominal distention. I think it will be wise for those who have not had much experience with this method of treatment to be prepared to operate in the first cases in which it is used or until such time as familiarity with its technic and with its possible limitations has been developed.

DR. FREDERICK A. COLLIER, Ann Arbor, Mich: About eight years ago, in the surgical section at the annual session, in a symposium on the treatment of intestinal obstruction, a young man read a paper on some experimental work on dogs. The discussion was led by the late great surgeon John B. Deaver, who said "Man is man and dog is dog, and never the twain shall meet." The poor laboratory worker passed out of the picture. There have been two notable contributions to the treatment of obstruction since that time, and both have come from the laboratory. Decompression as developed by Dr. Wangenstein and carried on by Dr. Johnston and Dr. Abbott is the greatest single technical contribution to abdominal surgery of the last decade. The second great contribution, given first by Dr. Hartwell and later by Dr. Hayden and Dr. Orr and other workers, showed the chemical changes brought on by vomiting in patients with obstruction. It is known that such patients may die from dehydration and from hypochloremia long before their lesion has passed beyond the control of the surgeon. During this year in the University Hospital my associates and I have interested ourselves in studying the question of salt loss and have found that hypochloremia is a real clinical entity that may kill. The normal value for plasma chlorides is about 560. If it falls below 500 symptoms begin to appear, and if it falls to the neighborhood of 300 the patient may die. One can suspect the presence of hypochloremia if the patient has been losing fluids from the gastrointestinal tract. The proof lies in the chemical determination of the plasma chlorides. There are, however, certain symptoms that suggest an imbalance of the chlorides; that is, in a patient who is not vomiting there will be loss of appetite, anorexia and later vomiting. The patient becomes depressed and confused mentally and may pass into coma. There is also a low pulse pressure. There are two situations to meet. When the patient has a normal value for chlorides when treatment is started and there are losses of fluid from the gastrointestinal tract due to enterostomy, fistula or duodenal suction, a volume-for-volume rule should be followed; that is, the substances drawn from the upper part of the gastrointestinal tract should be replaced liter for liter with physiologic solution of sodium chloride or Ringer's solution. The patient will then remain in chloride balance. On the other

hand, if the patient has been vomiting three or four days and the value for plasma chlorides is down, a rather simple formula may be followed which will replace the lost chlorides with a good deal of accuracy. Half a gram of salt per kilogram of body weight for each hundred points which the value for plasma chlorides is to be raised, given in the form of physiologic solution of sodium chloride, will bring the plasma chlorides to normal with accuracy. I wish to emphasize that many patients die of loss of chlorides as well as of dehydration. If one replaces the chlorides that have been lost, it should be remembered that they are always lost as hypotonic solutions, and one should use at least a physiologic solution of sodium chloride in replacing such fluids.

DR. CHARLES G. JOHNSTON, Detroit: We attempted in all these cases to follow the chloride level as well as to see that the patient had a definite fluid balance. I am happy that Dr. Collier brought out this point, because it is exceedingly important and was not discussed because of lack of time.

THE ETIOLOGY OF NAUSEA AND VOMITING OF PREGNANCY

PRELIMINARY REPORT

J. WILLIAM FINCH, M.D.

HOBART, OKLA.

This paper is a preliminary report on work being done to prove that nausea and vomiting accompanying pregnancy are due to an allergic reaction of the patient to the secretion of her own corpus luteum graviditatis.

This symptom complex is one which has been confronting the medical profession for centuries, the first record being made by Soranus of Ephesus¹ in the year 20 A. D.

Various authors² state that in from one half to two thirds of all obstetric cases there is nausea and vomiting to some degree during the first few months of pregnancy. So numerous have been the theories as to the etiology of this symptom complex³ that in this brief report no effort to discuss them will be made. The treatments recommended⁴ have been as variable and numerous as the theories of etiology.

The patient exhibiting nausea and vomiting may have these symptoms as a first indication of an existing pregnancy. The symptoms almost invariably begin between the third and the sixth week of pregnancy and gradually subside sometime near the fourth month of pregnancy.⁴ The symptoms may vary in severity from the mild case, so frequently seen, in which there is morning sickness with or without vomiting, to the moderate case in which there is nausea all day long, frequently vomiting, and extreme discomfort for weeks. Or the case may advance to the true hyperemesis gravidarum with a truly serious prognosis.

Hirst⁵ was the first to connect the nausea and vomiting of pregnancy with the functioning of the corpus luteum. He states that every woman during her menstrual life is constantly absorbing corpus luteum substance but that with the onset of pregnancy this absorption ceases. On this theory he administered

corpus luteum extract to a number of patients with surprisingly good results in alleviating or stopping their symptoms.

The corpus luteum, with impregnation, continues to develop instead of taking on the customary retrogressive changes during and after menstruation. The corpus luteum of pregnancy develops to a size much larger than the false corpus luteum; the colloid is more abundant in the organ and the granulosa cells are larger than before pregnancy.⁶ This enlargement takes place at the same time that symptoms of nausea and vomiting develop and the patient begins to be relieved of her symptoms about the fourth month, at which time retrogressive changes are taking place in the corpus luteum.

Considering that the development of the nausea and vomiting and the development of the corpus luteum of pregnancy occur at the same time and that the time of disappearance of the symptoms coincides with the time of retrogressive changes in the gland, I decided to conduct a series of tests on the theory that the nauseated and vomiting patient is allergic to her own hormone, develops her symptoms as a result of her sensitivity and returns to normal after the gland ceases to feed its secretion into her body in such quantity. On the same theory it can be assumed that Hirst was able to relieve his patients not by giving them a secretion in which they were deficient, as he assumed, but by desensitizing them and relieving them of their allergic reaction to the hormone.

Patients were tested by cleansing the skin with alcohol and injecting intradermally from 0.02 to 0.03 cc. of progestin in sterile cottonseed oil and recording reactions fifteen and thirty minutes later. Reactions were calibrated from negative to 4 plus, according to the size of the wheal and the surrounding erythema produced just as in intradermal injections of any food, drug or pollen extract or animal dander to determine a patient's degree of sensitivity. A control injection was made with sterile cottonseed oil in the same arm. The majority of the tests were made on the volar aspect of the forearm. A few patients were tested with a solution of progestin in sterile almond oil but the cutaneous reactions to the almond oil were so much greater than those to the cottonseed oil that the latter product was used in the remainder of the cases. One interesting notation has been that several of the pregnant patients who were nauseated and gave 3 or 4 plus reactions to the progestin intradermally have complained as late as five or six weeks after the intradermal injection that when they become nauseated severely the area of injection again becomes irritated and forms a wheal with a surrounding erythema and an itching sensation. I know of no way to explain this other than that the solution injected, being an oily one, is absorbed very slowly, and part of it remains in the skin for a protracted time. An extremely high percentage of the patients with nausea and vomiting of pregnancy gave a family history of allergy, as is noted in the reports of cases which follow:

REPORT OF CASES

CASE 1.—A secundipara, aged 27, who was nauseated with both former pregnancies, was very nauseated with the present pregnancy, vomited frequently. Nausea with each pregnancy began about the sixth week of gestation and lasted through the fifth month. Intradermal progestin gave a 4 plus reaction. The patient, her father, maternal grandmother and two brothers have seasonal hay fever and two sisters have asthma.

6. Hirst, B. C.: *A Textbook of Obstetrics*, ed. 8, Philadelphia, W. B. Saunders Company, 1918.

CASE 2.—A *tertipara*, aged 28, was moderately nauseated with her first three pregnancies. In this pregnancy nausea began about the fourth week and stopped at about four and one-half months. Nausea was moderate with no vomiting. Intradermal progestin gave a 2 plus reaction. The family history relative to allergy was not obtained.

CASE 3.—A *secundipara*, aged 31, was severely nauseated with her former pregnancies. In this pregnancy nausea began at about four weeks and was severe all day long with vomiting several times a week until about four and one-half months gestation. Intradermal progestin gave a 3 plus reaction. A brother has hay fever.

CASE 4.—A *primipara*, aged 30, was severely nauseated with her first pregnancy and vomited occasionally. She was moderately nauseated with this pregnancy with occasional vomiting. Intradermal progestin gave a 2 plus reaction. Nausea began at about one month gestation and ceased at about four months. The patient's parents died when she was an infant but she has one uncle with severe asthma.

CASE 5.—A *secundigravida*, aged 21, had one miscarriage at four months two years ago. She was mildly nauseated with that pregnancy. The cause of the miscarriage was unknown. The patient became extremely nauseated with this pregnancy at about one month gestation, vomiting almost all ingested food. Daily injection of extract of corpus luteum (each dose containing 0.02 Gm. of soluble extract) for twelve days resulted in complete cessation of vomiting, the patient having only transient periods of mild nausea after that time. Nausea completely disappeared at about four months gestation. Intradermal progestin gave a 3 plus reaction. There was no history of allergic diseases in the family.

CASE 6.—A *tertigraida*, aged 30, had one miscarriage at five months gestation three years ago, caused apparently by a long automobile trip. The patient has one child aged 19 months. She became nauseated with this pregnancy at about three weeks. She did not suspect pregnancy until nausea became intense with occasional vomiting. Intradermal progestin gave a 4 plus reaction. The patient's father has severe asthma. The patient is now receiving injections of progestin in oil, beginning with one-fourth international unit and gradually increasing at three day intervals to 2 international units. After three doses nausea was improved, and after five doses it had almost disappeared except for transient morning sickness.

CASE 7.—A woman, aged 26, miscarried twins at four months gestation six years ago following a large dose of an oxytocic drug self administered. She was greatly nauseated with frequent vomiting with that pregnancy. The present pregnancy was desired but the patient became intensely nauseated with frequent vomiting at about six weeks gestation. Nausea and vomiting ceased at about four and one-half months gestation. The patient's brother has seasonal hay fever and a nephew has asthma. Intradermal progestin six months before the patient became pregnant gave a 4 plus reaction. Intradermal progestin when the patient was at the end of the first trimester of pregnancy also gave a 4 plus reaction.

CASE 8.—A *primigravida*, aged 37, had tried for fifteen years to become pregnant without success. She became pregnant after the administration for three months of gonadotropic substance. She became extremely nauseated without vomiting at four weeks gestation, the symptoms increasing somewhat in severity until about the end of the first trimester and gradually diminishing during the fourth month of pregnancy. Intradermal progestin gave a 3 plus reaction. The patient's brother has severe migraine, as has also the patient.

CASE 9.—A *primipara*, aged 30, was not nauseated with her first pregnancy. With this pregnancy intense nausea with occasional vomiting began at about the third week of pregnancy. Nausea stopped at about the end of the fourth month. The patient's father has severe seasonal hay fever. Intradermal progestin gave a 4 plus reaction.

CASE 10.—A *tertigraida*, aged 21, became severely nauseated at about six weeks with her first pregnancy and had occasional attacks of vomiting. The symptoms subsided at about four

months gestation. The baby died at birth, apparently from poor obstetric care. With her second pregnancy she became nauseated at about six weeks and was nauseated severely with frequent vomiting until at three months she miscarried. With the last pregnancy the patient became nauseated at about six weeks gestation with about one vomiting spell a day. Nausea stopped at the end of the fourth month. The patient was delivered of a normal male infant at term. The patient's mother has asthma. Intradermal progestin gave a 2-plus reaction.

CASE 11.—A *primigravida*, aged 26, was extremely nauseated all day long with occasional vomiting from about six weeks until six months gestation. Repeated intradermal injections of extract of corpus luteum during the patient's period of nausea all gave a 4 plus reaction. The patient also has severe seasonal hay fever and has frequently suffered nausea with the first day or two of the menses. The patient was delivered of a normal male at term. Nine months after delivery an intradermal injection of progestin in oil gave a 3 plus reaction.

CASE 12.—A *primigravida*, aged 21, now about seven weeks pregnant, has nausea which began at about four weeks gestation; she is now nauseated all day long without vomiting. The odor of food nauseates her severely. The menses have always been every twenty-five days and of eight days' duration. The patient's maternal uncle has asthma. Intradermal progestin gave a 2 plus reaction.

CASE 13.—A *primigravida*, aged 24, is now about ten weeks pregnant. Nausea began at about three and one-half weeks gestation before the patient suspected pregnancy. At six weeks the nausea was intense with vomiting of practically all ingested food. At this time treatment was begun, 1 cc. of extract of corpus luteum (containing 0.02 Gm. of soluble extract) being given at forty-eight hour intervals for three doses, then one-half international unit of progestin in oil at the same interval for three doses, then 1 international unit, 1½ and 2 international units respectively at each of the next three doses. After the fourth dose the symptoms were markedly alleviated and at this writing the patient, having had the foregoing treatment, now has no vomiting and only transient attacks of mild nausea. The patient's father and sister both have severe seasonal hay fever. Intradermal progestin gave a 4 plus reaction.

CASE 14.—A woman, aged 29, who has one child aged 18 months, was nauseated slightly for about six weeks during the early part of that pregnancy but did not vomit. There was no history of allergy in the family. Intradermal progestin gave a 2 plus reaction.

CASES 15 to 20 inclusive.—The patients' ages ranged from 19 to 27 years; four are *primigravidas* and one is a *primipara*. In each case there was an extremely slight amount of nausea and no vomiting following about five or six weeks of gestation. The duration of the symptoms varied from five days to two weeks. There was no history of allergy in the families of any of these patients. Intradermal progestin gave a 1 plus reaction in all five cases.

CASES 21 to 24 inclusive.—The patients' ages ranged from 21 to 33 years; two are *primigravidas*, one is a *primipara* and one is a *quintipara*. None of these patients have had even the slightest degree of nausea or vomiting with the present or any previous pregnancy. There was no history of allergy in the families of any of these four patients. Intradermal progestin gave negative reaction in all cases.

CASE 25.—A virgin, aged 20, has seasonal hay fever. Her father has seasonal hay fever. The patient has had no nausea with the menses. Intradermal progestin gave a 1 plus reaction.

CASE 26.—A virgin, aged 20, with no history of allergy in her family, has had no nausea with the menses. Intradermal progestin gave a 1 plus reaction.

CASE 27.—A virgin, aged 21, with no history of allergy in her family, has had no nausea with the menses. Intradermal progestin gave a 1 plus reaction.

CASE 28.—A woman, aged 52, had a surgical menopause fourteen years ago. She has one child, now aged 30. With that pregnancy the patient had a very mild morning sickness. She had a normal menstrual history up to the age of 35 or 36, at

which time she had an operation for a fibroid uterus and ovarian cysts. There was no history of allergy in the family. Intradermal progestin gave a 1 plus reaction.

CASE 29.—A virgin, aged 15, whose menses began at 11 years and pubic hair developed at 9, had marked breast development at 10½. At 13 she began having extremely heavy periods and at 14 she had a curettage to stop a prolonged menstrual period. Curettings were of hyperplastic endometrium. Following this curettage the patient was normal for ten months, with the exception of two menses which lasted nine and twelve days respectively. At 15 the patient was seen with a heavy menstrual flow, which had existed for three weeks before she consulted a physician. Large doses of progestin checked the flow but curettage of the hyperplastic endometrium was necessary to stop it. The condition is now progressing normally with the administration of corpus luteum during the week before the expected menstrual period and with small doses of thyroid extract during the entire cycle. The symptoms are probably a result of oversecretion of estrogen from persistence of the graafian follicle, and, because of a probable lack of a normal amount of progestin throughout most of her sexual life, she should theoretically at least be nonsensitive to progestin. There is no history of allergy in the family. Intradermal progestin gave a negative reaction.

CASE 30.—An octipara, aged 44, was nauseated severely and vomited in moderate degree with all eight of her pregnancies. Her present complaint is eczema due to food allergy. The patient also has seasonal hay fever. Intradermal progestin gave a 3 plus reaction.

COMMENT

The menstrual history and progress in all the cases was negative unless otherwise stated in the reports.

This is only a preliminary report, but I believe that the uniformity of the results of the intradermal tests, the good results on the patients treated along the lines of allergic desensitization and the huge number of women afflicted with these symptoms at all times merits an investigation on a large scale. It would also be of interest to test with intradermal progestin a series of young girls before puberty.

I believe that patients presenting nausea and vomiting either have inherited directly a sensitivity to progestin or, more probably, have inherited the allergic tendency and become sensitive to their own corpus luteum secretion during their menstrual cycles or from the corpus luteum of a previous pregnancy.

If further investigation confirms these observations, one might well assume that a patient desiring pregnancy could be tested for sensitivity to progestin and, if found sensitive, could be desensitized before impregnation or before the corpus luteum of pregnancy reaches the stage of enlargement necessary to produce the symptoms of nausea and vomiting. This treatment would consist of graduated doses of progestin injected at closely spaced intervals until the patient is desensitized and the symptoms either do not develop or are relieved if they have already developed. It would be of further benefit, I believe, if a solvent other than oil could be used for the progestin, since the various oils now in use are more or less irritating to the skin of patients when injected intradermally and are slowly absorbed. A solution less irritating and more quickly absorbed would probably also enhance the treatment of nausea and vomiting along these lines by allowing intradermal injections to be given concurrently with the subcutaneous injections for desensitization.

SUMMARY

1. Nausea and vomiting of pregnancy develop at the same time at which the corpus luteum of pregnancy

reaches an appreciable size. The symptoms disappear at about the time the gland is known to begin retrogressive changes.

2. In a series of patients with nausea and vomiting of pregnancy in varying degrees when injected intradermally with from 0.02 to 0.03 cc. of progestin in oil a cutaneous reaction developed directly proportional to the severity of the symptoms.

3. A control series of patients who were not nauseated and in the pregnant state gave negative cutaneous reactions when tested in the same manner.

4. Patients treated with subcutaneous corpus luteum extract and progestin along the lines of allergic desensitization were gradually relieved of their symptoms.

5. A high percentage of the patients with nausea and vomiting of pregnancy either had other diseases of allergy or gave a family history of allergy.

CONCLUSIONS

1. The nausea and vomiting accompanying pregnancy is due to an allergic sensitivity of the patient to the secretion of her own corpus luteum of pregnancy.

2. Desensitization may be accomplished by injection of graduated doses of progestin, thus alleviating or stopping the patient's symptoms.

3. Intradermal testing may determine, even before pregnancy, whether a patient will or will not be nauseated when pregnant by determining whether or not she is sensitive to progestin.

SENSITIVITY TO RABBIT SERUM

AARON BROWN, M.D.

AND

PHILIP H. SECHZER, B.S.

NEW YORK

The purpose of this study was to determine whether rabbit serum can produce reactions of the skin and the eye that are significant.

The advantages of rabbit antipneumococcus serum have been well summarized by Horsfall and his co-workers.¹

In the first paper on the clinical use of rabbit serum, these authors² reported its administration in twenty-two cases of pneumonia and stressed the fact that the intradermal reactions to rabbit serum were not significant as an indication of sensitivity. Neither conjunctival nor intravenous tests were positive in this series of cases.

In the second paper, they³ reported on the use of rabbit serum in sixty-seven cases of pneumonia. They reiterated that no reliance had been placed on the results of intradermal tests because of the commonness of false positive reactions. A marked positive intradermal reaction occasionally occurs in persons subsequently shown not to be sensitive to rabbit serum on intravenous injection. These authors also stated that the conjunctival test has been of little aid in the judging of sensitivity, though a positive reaction should be regarded as an

From the Department of Medicine, New York University College of Medicine, and the Third Medical Division, Bellevue Hospital.

2. Horsfall, F. L., Jr.; Goodner, Kenneth; MacLeod, C. M. and Harris, A. H.: Antipneumococcus Rabbit Serum as a Therapeutic Agent in Lobar Pneumonia, *J. A. M. A.* 108: 1483 (May 1) 1937.

3. Horsfall, F. L., Jr.; Goodner, Kenneth, and MacLeod, C. M.: *New York State J. Med.* 38: 245 (Feb. 5) 1938.

indication that all subsequent procedures should be undertaken with the greatest caution. They expressed satisfaction with the intravenous test, though two of the sixty-seven patients reacted positively to it.

The conjunctival test has been relied on as a guide in the use of antipneumococcus horse serum. We should expect rabbit serum to follow the same rule.

To determine whether it does, we performed intradermal and conjunctival tests on 101 patients. Since allergic persons are more apt to give reactions, we chose to carry out the work with the allergic patients in the clinics of the Bellevue Hospital and the New York University College of Medicine.

Intradermal and conjunctival tests with normal rabbit serum diluted 1:10 and containing 0.5 per cent chlorobutanol were performed on 101 patients. The conjunctival test was done by instilling 1 drop of serum into the lower conjunctival sac of the right eye. The intradermal test consisted of the raising of a $\frac{1}{8}$ inch (0.32 cm.) wheal in the skin of the arm by an injection of from 0.02 to 0.01 cc. Because every patient had one or more negative intradermal reactions, controls of diluting fluid were used only when it was necessary to differentiate a dermatographic skin. The reactions were read in from ten to fifteen minutes, as follows:

0—no reaction

1 plus—erythematous flare and/or slight wheal

2 plus—definite wheal from 1 to 2 cm. in diameter

3 plus—wheal from 1 to 2 cm. in diameter with no/or slight pseudopodia

4 plus—wheal 2 cm. in diameter or larger, with marked pseudopodia

Conjunctival tests were regarded as positive or negative.

This series of 101 patients contained fifty-four males and forty-seven females, with the age ranging from 11 to 79 years.

The tests with rabbit serum gave sixty-nine negative intradermal reactions, twenty-two flare reactions, six 2 plus reactions, two 3 plus reactions and two 4 plus reactions. Only one person gave a positive conjunctival reaction in addition to the 4 plus intradermal reaction. This patient gave an immediate positive intradermal and conjunctival reaction, followed within five minutes by a systemic reaction, with urticaria, angioneurotic edema and asthma, requiring repeated injections of epinephrine for relief. These symptoms persisted in a mild way for several days, requiring the continued use of ephedrine, augmented by occasional administration of epinephrine.

We feel that the intravenous injection of rabbit serum in this case might have been fatal.

SUMMARY

Intradermal and conjunctival tests with rabbit serum were performed on 101 allergic patients. One person gave a systemic reaction to the conjunctival test, and the increasing use of rabbit serum prompts us to urge caution in the administration of this agent.

The conjunctival reaction, we feel, is a good indicator of general sensitivity, and while fewer persons may be sensitive to rabbit serum than are sensitive to horse serum, nevertheless we feel that the same care should be used with rabbit as with horse serum.

39 West Fifty-Fifth Street.

SULFANILAMIDE TREATMENT OF TRACHOMA

PRELIMINARY REPORT

FRED LOE, M.D.

ROSEBUD, S. D.

In August 1937 my associates and I began to use sulfanilamide in the treatment of trachoma at the Rosebud Indian Hospital. For the experiment we selected two patients whose condition had been diagnosed as trachoma by an eye specialist in the Indian Service and by several other physicians in the Indian Service who are especially experienced with trachoma. One of the two patients had had trachoma for two years, the other for eighteen months. Both patients had had grattage, followed by treatments with silver nitrate given intermittently during the period of their infection, with no noticeable improvement. On the basis of their body weight they were given one-third grain (0.02 Gm.) of sulfanilamide, with an equal amount of sodium bicarbonate, a pound daily for ten days. Then the dose was decreased to one-fourth grain (0.016 Gm.) of sulfanilamide a pound daily for fourteen days. No other medication was allowed during this period. Within five days after treatment was begun we were able to see changes in the conjunctiva; the redness gradually disappeared, the granules and papules decreased in size and the blood vessels became increasingly visible. With a maintenance dose of one-fourth grain of sulfanilamide a pound daily these two patients were apparently cured of trachoma within one month. To date neither has shown signs of recurrence.

On Jan. 6, 1938, we started sulfanilamide treatment with thirteen patients who had been under continuous treatment for trachoma for periods varying from one to seven years and who were picked for the purpose from a group of patients with trachoma. Three were dismissed on January 16, apparently cured; the remaining ten were found to be greatly improved after being under treatment for eight days and were treated for two weeks longer.

After using sulfanilamide in the aforementioned dose for the treatment of trachoma in 140 patients, we are able to summarize briefly the improvements noted:

1. Improvement of subjective symptoms:

(a) Cessation of lacrimation within twenty-four hours.

(b) Loss of photophobia within twenty-four hours.

(c) Improvement of vision within seventy-two hours in cases of pannus.

2. Improvement of objective symptoms:

(a) Paling of the conjunctiva.

(b) Paling of the trachomatous patches and flattening of the granules and follicles. At the end of three weeks of treatment a few flat-topped granules remained, and we found that only after several months did these entirely disappear. The medication was not continued during these several months, however. The ninety-three patients treated in boarding schools during January and discharged as improved are examined at monthly intervals and continue to show improvement in the conjunctiva without further medication and with no exacerbations of any kind. Examination May 12 showed twelve with slight activity.

(c) In the cases in which there had been no scarring from instrumentation, the conjunctiva at the end of two months apparently resumed its normal velvety texture.

Read before the Section on Ophthalmology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

(d) The blood vessels of the conjunctiva become more visible on the fifth or sixth day of treatment, and daily thereafter they become more normal.

(e) In thirty cases of pannus treated in the hospital we noted that the opacity began clearing between the eighth and the fifteenth day, depending on the density of the pannus, with great improvement of vision.

(f) The granules on the lower lids were found to be the last objective symptoms to disappear.

Our work with sulfanilamide in the treatment of trachoma has to date been done with 140 patients, all either hospitalized or under the close supervision of nurses in our three boarding schools. The reactions have been surprisingly few and mild. In three cases dermatitis developed. Three days after withdrawal of the sulfanilamide this cleared up, leaving no sequelae. Four patients complained of mild vertigo and headache. Withdrawal of the sulfanilamide for twenty-four hours cleared these symptoms, and the patients were able to resume treatment. We noted no elevation of temperature coincident with the administration of sulfanilamide.

Our experience with this method of treatment thus far has made us extremely sanguine. It is still too early to speak of the results as "a cure," for we do not know whether there will be recurrences or not. Moreover, not all patients respond alike, so that standardization of treatment is as yet impossible. Consequently, we offer our observations in the nature of a preliminary report, with the hope that this method of treatment will be used by others and in a number of cases sufficiently large to determine the exact value.

REPORT OF CASES

CASE 1.—H. R. B., a full-blooded Sioux, who was 52 years old, weighed 81.1 Kg. and had a negative Wassermann reaction, had suffered from chronic trachoma since April 1932 and had been hospitalized for treatment for a total of 104 days prior to admission Jan. 24, 1938. In March 1933 a grattage was done, which was only partly palliative, for it was followed in November 1933 by stretching of the conjunctiva and rubbing gauze over the roughened lids. Intermediate treatment consisted of irrigation with zinc and boric acid solutions alternated with instillations of 1 per cent silver nitrate. In spite of this rather persistent treatment, by October 1936 the conjunctiva of each lid was thickened, opaque and replaced by scars; pannus extended over the anterior surface of the cornea. There were numerous granular patches on the lids, no visible blood vessels in the lids, marked photophobia and dense pannus extending over the upper half of the cornea, and the patient was unable to read print, for his vision could not be corrected on account of the pannus. The vision of the left eye was 20/160 and of the right eye 20/40. February 7 the vision of both eyes was 20/30. February 8 the vision of the right eye was 20/30 and of the left eye 20/20. February 12 the vision was normal, the lids were clearing and numerous blood vessels were visible in the conjunctivas.

CASE 2.—V. L. W., of three-fourths Sioux blood, who was 47 years old, weighed 81.1 Kg. and had a negative Wassermann reaction, had suffered from trachoma since childhood. The family history revealed that both parents and three siblings had trachoma. The patient's mother was totally blind during the last decade of her life. Examination on admission Feb. 3, 1938, showed only light perception in the right eye. The patient could distinguish fingers with the left eye at a distance of 15 inches. The pupils were completely obscured because of corneal pannus. The patient complained of severe photophobia; intense lacrimation was present. February 4 the administration of sulfanilamide was started. By February 7 the patient could distinguish the correct number of fingers at 40 inches with the left eye. With the right eye he could see the examiner's hand at 36 inches. February 8 he could read the top line and

the first three letters of the second line on Snellen's chart at 10 inches. February 12 his reading ability remained the same. Some blood vessels were visible; the lids were less red; the pupils were visible to the examiner. The patient volunteered the information that his vision had improved to the extent that he was able to see more than ever before in his life. February 15 he read the first and second lines at 28 inches and he now has coarse vision, being able to see his way about the ward and to the bathroom. He says that his eyes are not painful and that there is no photophobia.

ABSTRACT OF DISCUSSION

DR. HARRY S. GRADLE, Chicago: Stimulated by the original report of Dr. Loe to the Department of the Interior on the effects of sulfanilamide in trachoma among the Indians, I started a series of cases in my own trachoma clinics with that drug. Twenty-five cases were selected among the patients in the Trachoma Clinics of Southern Illinois, where all are outpatients, and sixteen in the Illinois Eye and Ear Infirmary, all of whom remained in the hospital. Of this number, five were forced to discontinue the drug within a few days because of systemic symptoms that ranged from mere headache and nausea to actual cyanosis, necessitating digitalis. The cases in the infirmary hospital were followed from the laboratory standpoint daily with the following observations: (a) Bacteriologically, there were organisms found in only a few cases. (b) The hemoglobin showed a fairly uniform decrease of from 10 to 15 per cent. (c) The red blood count showed no change except for a moderate decrease in isolated cases. (d) The white blood count showed a fairly uniform decrease of from 1,000 to 3,000 cells. With regard to the impressions gained from three weeks' observation of these cases under sulfanilamide, without any local treatment except a cleansing wash with physiologic solution of sodium chloride, the following seemed to be the salient features: 1. Trachoma II and III responded fairly uniformly in a most surprising fashion in that the velvety patches and hypertrophies disappeared in short order. The thickened and hyperemic conjunctiva became thinner and pale, the individual vessels became visible, and the secretion disappeared in the majority of cases. The results of three weeks of sulfanilamide approximated those of from three to six months of local treatment, but without scar formation. 2. Regardless of the stage, photophobia and lacrimation disappeared in short order. This subjective improvement was most striking and, to the patients, most gratifying. 3. In trachoma IIb and IIIa and IIb there was a marked improvement in vision in cases in which the vision was decreased because of pannus. In the older and more malignant cases and those in which there were corneal scars due to old ulcers, the visual improvement was negligible. But in some instances the visual results were almost miraculous. 4. In trachoma IV and in malignant cases of trachoma IIb, practically no improvement could be noted. It would appear that in the use of sulfanilamide we have a new means of combating the more acute stages of trachoma. The drug is not without danger and should be taken only when medical observation is possible every twenty-four to forty-eight hours.

University Tradition in America.—From the first foundations to the present, four main streams have watered the soil in which the universities have flourished. These ultimate sources of strength are, first, the cultivation of learning for its own sake; secondly, the general educational stream of the liberal arts; thirdly, the educational stream that makes possible the professions; and, lastly, the never-failing river of student life carrying all the power that comes from the gregarious impulses of human beings. All four streams are easily discerned bringing life to the English universities in the first half of the seventeenth century. For this reason Oxford and Cambridge flourished; and because they flourished, their sons who migrated to this strange land desired to cultivate the same sturdy tradition even in a wilderness.—James Bryant Conant in the Tercentenary of Harvard College, Cambridge, Mass., Harvard University Press, 1937.

Clinical Notes, Suggestions and New Instruments

PNEUMOCOCCUS TYPE VII MENINGITIS, TREATED WITH SULFANILAMIDE AND SPECIFIC SERUM, WITH RECOVERY

RICHARD Z. QUERY, M.D., DURHAM, N. C.

Pneumococcic meningitis has been considered an almost universally fatal disease, the mortality being about 95 per cent. Clinical observers have reported occasional cures by the use of type specific antipneumococcus serum or by the use of ethylhydrocupreine hydrochloride. These two therapeutic agents in combination have been used in a few additional cases, but the results are far from gratifying. Recoveries are so rare that they usually gain access to the medical literature.

Experimenters have demonstrated that sulfanilamide has a bacteriostatic and bacteriocidal action on pneumococci both in vivo and in vitro. Rosenthal¹ found that the drug was quite effective in peritonitis in the mouse caused by pneumococcus types I, II and III, results which were confirmed by Long and Bliss.² Cooper and Gross³ produced type III pneumonia in mice and noted that the mortality rate was decreased and the survival period prolonged in those which did succumb. In fact, these observers report that sulfanilamide is just as effective as the type specific pneumococcus serum and, further, that the combination of sulfanilamide and pneumococcus antiserum gave better results than either of these measures used individually. Heintzelman⁴ studied nine cases of type III lobar pneumonia treated with sulfanilamide in which there was a mortality rate of 22 per cent, whereas in ten similar cases in which symptomatic treatment was given the mortality rate was 74 per cent.

As to the efficacy of sulfanilamide in the treatment of other forms of purulent meningitis, excellent results are being reported. In some of the most hopeless cases of streptococcic and meningococcic meningitis remarkable cures have been effected. So far I have been able to find only two reports⁵ in the medical literature of the successful use of this new drug in cases of pneumococcic meningitis.

It is my purpose in this paper to report a case of type VII pneumococcus pneumonia and meningitis in which the combination of antiserum and sulfanilamide caused a dramatic cure.

REPORT OF CASE

History.—A Negro, aged 33, a worker in a tobacco factory, admitted to Duke Hospital Nov. 11, 1937, complained of pain in the right chest of two days' duration.

The family, marital and past histories were irrelevant.

Eleven days before admission he contracted an infection in the upper part of the respiratory tract following exposure to cold, damp weather. Two days before admission he noticed the onset of generalized bodily aches, fever and sharp pains in the right anterior part of the chest during a deep inspiration. The cough,

which he had had from the beginning of his illness, became more productive and sputum was described as blood streaked. He did not have a chill. These symptoms increased in severity until admission.

Examination.—The temperature was 38 C. (100.4 F.), pulse rate 108, respiratory rate 30 and blood pressure 125 systolic, 88 diastolic. The patient was well developed, well nourished and obviously acutely ill. He was in slight respiratory distress but there was no cyanosis of the lips or nail beds. He coughed frequently, producing a moderate amount of blood-streaked sputum.

Expansion of the right side of the chest was limited. Tactile fremitus was increased over the right lower lobe posteriorly. The percussion note was dull over this area; the breath sounds were bronchovesicular; many fine rales were heard at the end of inspiration. The remainder of the general physical examination was negative.

Accessory laboratory examinations showed hemoglobin 14.2 Gm. (Sahli), red blood cells 4,750,000 and white blood cells 11,000, of which 95 per cent were polymorphonuclear neutrophils with a preponderance of young forms. The urine showed

Course in case of pneumococcus type VII meningitis.

1 plus albumin. The Wassermann and Kahn reactions of the blood were negative. A smear of the sputum showed many gram-positive encapsulated lancet-shaped diplococci. Typing of the sputum by the Neufeld method demonstrated type VII pneumococci. This was confirmed by mouse inoculation and retyping. A blood culture taken on admission was reported the following day as showing innumerable colonies of type VII pneumococci. A film was taken by a portable x-ray machine which showed diffuse clouding throughout the lower two thirds of the right lung and slight mottling extending out from the left hilus. The general appearance was that of bronchopneumonia.

One hour after admission type VII antipneumococcus serum was administered intravenously, and during the course of the next fourteen hours 220,000 units was given, with some improvement. Eighteen hours after admission the patient became drowsy and complained of severe headache. It was found at this time that his neck was stiff and Kernig's sign was positive. A lumbar puncture was done. The cerebrospinal fluid was under increased pressure and turbid. The Pandy test was positive. There were 730 cells, predominantly polymorphonuclear neutro-

4. Heintzelman, J. H. L.; Hadley, P., and Mellon, R. R.: Am. J. M. Sc. 193: 759 (June) 1937.

5. Caldwell, J. R., and Byrnie, P. S.: Brit. M. J. 1: 1204 (June 12) 1937. Latté, Conrad, ibid. 1: 566 (March 12) 1938.

phils; the smear revealed many gram-positive encapsulated diplococci. The spinal fluid culture was positive for type VII pneumococci.

The patient was started on sulfanilamide by mouth, 4 Gm. being given on the first night, 18.2 Gm. the second day and 19.5 Gm. the third day. The concentration of sulfanilamide in the blood and spinal fluid reached 23 and 16 mg. per hundred cubic centimeters respectively. The methemoglobin was 40 per cent, as shown in the accompanying chart. On the fifth day he became completely maniacal and restraints were applied. It was impossible to give medication by mouth, so sulfanilamide was given by subcutaneous infusion in 1 per cent solution, with a corresponding decrease in the concentration of the drug in the blood and spinal fluid. Type VII antipneumococcus serum was again given intravenously and 60,000 units intrathecally. By the tenth day the mania had disappeared and he was able to take medication and nourishment by mouth, and the sulfanilamide dosage was increased. During this time he was showing rapid clinical improvement but was disoriented as to time and place. On cessation of the sulfanilamide his sensorium completely cleared.

On his seventeenth hospital day signs of fluid were demonstrated at the base of the right lung; 450 cc. of thick, greenish fluid was removed in which gram-positive diplococci were demonstrated. Culture of this fluid revealed type VII pneumococci. Tidal irrigation was instituted and an uneventful recovery ensued.

Follow Up.—The patient was seen five months after discharge from the hospital. He had gained weight and was feeling perfectly well. He had no headaches, convulsions or other residual effects that could be ascribed to the meningitis.

SULFANILAMIDE THERAPY FOR SUPPURATIVE PYLEPHLEBITIS AND LIVER ABSCESES

REUBEN OTTENBERG, M.D., AND MAURICE BERCK, M.D., NEW YORK

Suppurative pylephlebitis with multiple liver abscesses is an extremely grave disease. It most commonly follows acute appendicitis but also may complicate a great variety of intra-abdominal and rectal infections. The diagnosis may be difficult, and in many more cases the disease is recognized on the postmortem table rather than during life. The incidence of the condition has been appreciably smaller in recent times, owing to earlier operative intervention for acute appendicitis. In the older statistics necropsy reports of patients dead of acute appendicitis revealed pylephlebitis and liver abscesses in 4.7 per cent (Fitz),¹ 5 per cent (Armstrong)² and 5 per cent (Petren).³ More recent analyses showed 0.4 per cent (Gatch and Durman)⁴ and 0.3 per cent (Hawkes).⁵ Colp,⁶ in analyzing 2,841 cases of acute appendicitis, noted an incidence of 6.8 per cent of preoperative chills; in only a small fraction of these cases did the condition progress on to the septic course of pylephlebitis. He found that a single preoperative chill was of little prognostic importance. However, when pylephlebitis subsequently developed there was usually a preoperative history of multiple and protracted chills. In the case of early acute appendicitis in which there has been but a single chill there is usually locally contiguous phlebitis of the appendicular veins. Early operation succeeds because it eradicates the local phlebitis by removal of the appendicular mesenterium in the course of appendectomy.

6. Colp, Ralph: The Treatment of Pylephlebitis of Appendicular Origin, Ann. Surg. 85:257 (Feb.) 1927.

In isolated instances spontaneous recovery has occurred when multiple liver abscesses were thought to be present.⁷ However, doubt must always exist as to the nature of a condition regarded as suppurative pylephlebitis when recovery has occurred without laparotomy and examination of the liver. In a few instances operative drainage of liver abscesses due to appendicitis has resulted in recovery.⁸ Cases in which appearances at necropsy were regarded as those of healed suppurative pylephlebitis have been recorded.⁹

Operative intervention to treat the condition by ligation of branches or the main trunk of the portal vein has been attempted in many instances. These procedures have consisted chiefly (1) of ligation of the ileocolic vein at the time of appendectomy¹⁰ if a history of chills and the operative evidence of progressive thrombosis of the contiguous venous radicles were present, and (2) of ligation of the ileocolic superior mesenteric or portal veins (Braun,¹⁰ Colp,⁶ Taylor) in those instances in which suppurative pylephlebitis occurred as a later complication. The results of operative intervention (except as a primary prophylactic operation for restricted thrombophlebitis in the appendical area)¹¹ have been most disappointing.

The general consensus is that suppurative pylephlebitis with multiple liver abscesses is almost invariably fatal.⁷ The prognosis with any form of therapy is considered uniformly bad.

The micro-organisms seen at autopsy are of intestinal origin—usually colon bacilli, streptococci or various anaerobes. Of these the colon bacilli at least are known to be susceptible to sulfanilamide therapy.¹² It was this fact that led us to try the drug in the present cases.

It is our purpose in this communication to report two cases—the first of probable, i.e., clinically diagnosed, pylephlebitis following incision of an infected thrombosed hemorrhoid; the second of postappendical suppurative pylephlebitis with multiple liver abscesses (proved by biopsy of the liver). In both cases sulfanilamide therapy was followed by recovery.

REPORT OF CASES

CASE 1.—O. N., a man, aged 23, with a clinical diagnosis of pylephlebitis following an operation on an infected hemorrhoid, was admitted Sept. 22, 1937, and discharged October 24. He complained of fever, chills and abdominal pain. Two weeks before admission an infected thrombosed hemorrhoid had been incised by his private physician. Local pain had persisted. Six days before admission he suddenly experienced a severe chill and a temperature of 103 F. He then experienced fever and one or two chills a day with abdominal pain. When first seen he was having a chill and his temperature was 104 F. On physical examination there were shock tenderness over the liver and rebound tenderness over the right costal margin. On rectal examination there was a healing sinus leading up to an area of induration and tenderness in the anterior wall. The blood count showed hemoglobin content 105 per cent, red cells 5,300,000, white cells 13,250, polymorphonuclear leukocytes 68 per cent (33 per cent segmented, 35 per cent staff) eosinophils 1 per cent, monocytes 1 per cent, lymphocytes 30 per cent. The administration of sulfanilamide was started immediately, 1 Gm. every four hours for the first three days, then 0.5 Gm.

every four hours for the following two weeks and until his temperature had been normal for five days.

During the first two weeks of treatment he was very ill, with an irregular temperature ranging from 102 to 104 F. He showed a moderate grade of jaundice during the first week, the urine showing traces of bile and urobilinogen to a dilution of 1:250. The blood bilirubin was 1.6 mg. per hundred cubic centimeters and the direct van den Bergh test gave a negative reaction. The patient had only one chill after his admission to the hospital; this was accompanied by a temperature of 104 F. after one week of treatment. During the second week of treatment the temperature gradually fell to normal and remained normal thereafter. The tenderness over the liver and the jaundice disappeared and the patient proceeded to make a complete recovery.

CASE 2.—T. C., a man, aged 40, a Puerto Rican with a clinical diagnosis of postappendical suppurative pylephlebitis with multiple liver abscesses, was admitted Dec. 29, 1937, and discharged Feb. 25, 1938. Three days prior to admission he began to experience generalized abdominal pain of increasing severity. The next day two shaking chills occurred. The following day generalized pain and pain in the right lower quadrant became more severe. On admission the temperature was 101.2 F. and the pulse rate 120. Tenderness and rigidity were present in the right lower quadrant of the abdomen. The diagnosis was acute appendicitis with diffusing peritonitis. Appendectomy and drainage were performed for acute gangrenous ruptured appendicitis with diffusing purulent peritonitis. (Culture of peritoneal pus yielded *Bacillus coli*.) For the first week the temperature ranged from 101 to 102 F. On the ninth day there were a sudden rise of temperature to 103 F., jaundice and chilly feelings. On the tenth day there was a definite shaking chill. From the tenth to fifteenth day there was definite jaundice. The icteric index was 22 (acetone method). The white blood cells numbered 23,600 with polymorphonuclear leukocytes 88 per cent. For three weeks the patient experienced a septic type of fever, the temperature rising to 104 F. almost daily, frequent chills and progressive tender enlargement of the liver. During this period, blood cholesterol was very low (from 80 to 95 mg. per hundred cubic centimeters), with only traces of cholesterol ester. Sulfanilamide therapy was started twenty-four days after the onset of the septic symptoms. Two days after the beginning of this therapy exploratory laparotomy was done because of progressive tenderness in the right upper quadrant, which seemed to point to liver abscess. Microscopic section of the liver taken at biopsy is shown here.

At operation the liver was found to be grossly and uniformly enlarged by approximately 30 per cent of its normal size. The surface was smooth and the color mottled and a dark purplish red. Palpation revealed the subphrenic space entirely clear. The organ was extremely soft. There were innumerable nodular masses, approximately 2 cm. in diameter, scattered throughout the substance of the liver, presumably multiple small liver abscesses. The substance of the liver was extremely friable, as was evidenced when passage of the palpating hand was made over the left lobe of the liver and traction on the ligamentum teres caused an inadvertent rent in the anterior margin of the liver.

No therapeutic procedure being possible, a biopsy specimen approximately 1.5 cm. in diameter was taken from the margin of the traumatic rent in the liver, as already noted. Bleeding was controlled by the passage of a widely placed plain catgut suture passed with the blunt "liver" needle. Aspiration of the gallbladder for chemical analysis for the content of sulfanilamide was then done by passing the aspirating needle through the right lobe of the liver to enter the gallbladder on its superior nonperitonealized aspect. Here there was no possibility that bile would leak into the peritoneal cavity through the site of puncture of the gallbladder. Ten cubic centimeters of dark bile was withdrawn to be analyzed for its content of sulfanilamide. (This was later reported as 2.5 mg. per hundred cubic centi-

mers.) Aspiration of the liver substance was then done for bacteriologic culture. (This culture showed no growth.) Closure of the laparotomy wound was then done in the usual manner.

Sulfanilamide therapy was continued (6 Gm. the first day, 5 Gm. the second day, and 4 Gm. a day thereafter until the patient had been afebrile for two weeks; then 2 Gm. a day for one week further). Three days after the biopsy (five days after the beginning of the sulfanilamide therapy) the temperature had declined by lysis, and it remained at the level of from 99 to 100 F. for several weeks. It remained normal for ten days after the cessation of sulfanilamide therapy. The patient was then discharged. The hemoglobin content, white blood cell count and granulocyte count were closely watched throughout the course and at no time showed a noticeable depression.

Microscopic section of biopsy specimen taken from the liver in case 2, demonstrating endophlebitis with beginning thrombosis of intrahepatic portal radicles and perivenous abscess formation. (Dr. Paul Klemperer.)

During the course of sulfanilamide therapy chemical analysis of the blood revealed a sulfanilamide concentration of 6 mg. per hundred cubic centimeters.

SUMMARY AND CONCLUSIONS

Two patients with suppurative pylephlebitis and liver abscesses recovered under sulfanilamide therapy. In the first case, the diagnosis was purely clinical, since exploratory laparotomy was not done. In the second case, the diagnosis was proved by biopsy of the liver at an exploratory operation. Examination of the biopsy revealed endophlebitis of the intrahepatic portal radicles and perivenous liver abscesses, shown in the microscopic section. The infection in this case was due to the colon bacillus, an organism known to be susceptible to sulfanilamide therapy.¹³

From this experience we believe that a further trial of this form of therapy in these otherwise almost hopeless cases is warranted.

THE PATHOLOGY OF VITAMIN C DEFICIENCY

GILBERT DALLDORF, M.D.

VALHALLA, N. Y.

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

The primary morphologic effects of vitamin C deficiency occur in the intercellular substances of certain mesenchymal derivatives. These can best be described in terms of the prototype of these structures, loose connective tissue. Under normal conditions the type cell, the fibroblast, lies in an amorphous ground substance within which fibrils (reticulum) are formed which may in turn become gathered into wavy bands of collagen. In this transformation the fibrils seem to become cemented together by a translucent matrix, the formation suggesting a colloid phenomenon, the setting of a gel. It is precisely this phase of the formation of intercellular materials which may be completely controlled by vitamin C. Thus in guinea pigs which have been depleted of vitamin C the ground substance and fibroblasts are present as in health but fibrils or collagen are not formed. When the deficiency is satisfied, translucent bundles and masses of collagenous materials reappear within eighteen hours. The formation of intercellular material of bone (osteoid tissue) and of teeth (dentin) may be similarly controlled by withholding or supplying vitamin C.

These changes have been accurately studied¹ and observed by various pathologists. The observations on experimental animals are in perfect harmony with the observations of spontaneous scurvy in man.² A point that is still disputed is whether the vitamin directly affects the intercellular colloids or the cells. Collagen may form in the absence of fibroblasts,³ but in the primary response to treatment in scurvy the newly formed material is seen in proximity to the fibroblasts or their processes.⁴ While the cells are not significantly altered in appearance when the phenomena just described are taking place, they are altered during the late stages of chronic scurvy. Decision must be reserved on this point. Because the vitamin is assumed to have a pronounced effect on oxidation-reduction phenomena in the tissues and because hydrogen ion concentration is of critical importance to colloidal systems, it is tempting to accept the simpler explanation that the vitamin directly alters the physical character of the intercellular fluids.

Defective intercellular substances are seen in connective tissue, bones and teeth and are believed to

occur in the blood vessels. An interesting modification of the process is apparent in partial deficiency, wherein a substitute material forms in the teeth in place of dentin. This has been spoken of as "osteodentin," since it resembles both materials. Similarly, in the bones, collagenous material appears in partial deficiency in place of osteoid. The tendency is for defective materials to form in connective tissue in partial depletion, and for nothing of a substantial nature to form in complete depletion. Further involution of the tissues in complete deficiency does not occur because the animals die.

Morphologic changes have not been detected in the capillaries and it is doubtful whether they occur. Capillaries originate from embryonic connective tissue and it is not surprising that they are affected. But where the weakness occurs is unknown. The endothelium of capillaries is believed to be fused together by a cement substance, but the capillary is also accompanied and surrounded by connective tissues and thin collagenous fibers ensheath the endothelium. Whether the effect of the deficiency is on the sheath or on the endothelial cement substance has never been decided. As in the case of the connective tissues the parenchymal cells appear to be normal and may multiply. Thus in young granulation tissue during depletion capillary budding has been seen; but this attempt at regeneration is soon aborted, presumably by lack of intercellular materials.⁵

The anatomic manifestations of scurvy are greatly modified by two factors, growth and stress. These are of such importance to the pathology of vitamin C deficiency that they must be discussed in some detail.

Growth so modifies the anatomic picture in scurvy that for 200 years the disease in children and infants was considered a variety of rickets, a condition which it superficially resembles more closely than it does adult scurvy. Hematomas become less and less frequent as the age of the patients increases. It is in the young, growing animal that bone pains occur; in the adult they are rare. Osteoporosis is greatly intensified in the young animal, just as it is always most pronounced at the particular part of the bone where growth is most active. Moreover, the most rapidly growing bones at the particular age at which scurvy occurs are most affected. This distribution and exaggeration of the lesions are similar to what occurs in rickets.

Stress modifies the site of the lesions and determines the extent and involvement of the various structures. Individual lesions can best be understood if the lines of force are borne in mind. Stress plays a major part in determining the site of the hemorrhages; the pressure of boots or a diaper, the location of a vessel near a bony prominence—these are the factors which determine whether or not hemorrhages will occur. The hemorrhages and other changes in muscles depend on stress.⁶ In olden days it was noticed that blacksmiths and wool carders developed lesions in the shoulders and arms, soldiers in the calf and lumbosacral muscles.⁶

Lesions are indirectly modified by other factors, for example the presence or absence of a variety of other diseases (the list is long and rapidly growing and includes many infectious diseases, lobar pneumonia, typhoid and tuberculosis among others) and disturbances associated with an increased metabolic rate. These may operate similarly to growth and physical

stress (activity) in determining the requirements of vitamin C and therefore, indirectly, the extent and degree of the scorbutic lesions. It would be instructive to determine whether the vitamin enters directly into inflammatory phenomena. There is substantial evidence to support the view that it is essential to the formation of blood cells,⁷ including the granular leukocytes, and in this manner at least may be consumed at a higher than normal rate during infectious disease. Review of the larger series of cases of scurvy strongly encourages the belief that severe infectious diseases and scurvy go hand in hand and that each influences the severity and duration of the other.⁸

If the influence of growth and stress is borne in mind, the individual lesions of scurvy may be described without note being taken of modifications and exceptions that may or may not occur because of these influences.

BONES

Skeletal lesions are commonest in the costochondral junctions, the distal end of the femur, the proximal end of the tibia, femur and wrist. The distal humerus and proximal ulna are usually spared. In the affected regions bone formation (enchondral bone growth) ceases and the existing osseous shell becomes rarefied, widened and conical. The epiphysis is not affected, at least in early stages, but may become displaced. False motion occurs in advanced cases and probably in even moderately severe cases in the costochondral junctions of the ribs. Microscopic examination reveals a rarefaction of the existing cortex, cessation of bone growth and replacement of the normal junction by a zone of collagen-poor connective tissue in which are embedded fragments of densely calcified cartilage matrix, bare of osteoid tissue. In controlled material it has been shown that the connective tissue cells of the marrow are migrated osteoblasts which have reverted to fibroblasts. The process suggests that in the absence of vitamin C the osteoblasts, unable to form osteoid tissue, revert to their prototype and attempt to form a fibrous union between diaphysis and epiphysis. This zone is generally spoken of as the "gerüstmark," or framework marrow, and in it lie the densely calcified fragments of cartilage matrix and bony trabeculae which are so conspicuous in roentgenograms. This is also the classic anatomic lesion of scurvy and may be found, in infants and children, in early or moderately advanced cases of the disease although frequently several bones must be searched. Frequently this kind of lesion is complicated by hemorrhages, either large subperiosteal ones or small ecchymoses within or along the bone. In incompletely developed lesions, hemorrhages may be the deciding factor in an anatomic diagnosis.

If suspiciously enlarged costochondral junctions are submitted to microscopic examination, various stages of the typical scorbutic lesion will frequently be found. It is not necessary that it be fully developed. Experience rapidly recognizes a general fragility of the connective tissue fibers, a suggestive watery zone about the older osteoblasts and a defective osteoid tissue formation which plainly indicate the presence of scurvy. The greatest difficulties occur when scurvy is complicated by other diseases, for example rickets. It is at times difficult to distinguish scurvy from other dystrophies of bone such as osteogenesis imperfecta. Some of the latter conditions may indeed be related to the supply of vitamin C.

The periosteum shows a weakening of its attachment and a furious effort of connective tissue cells to reinforce it. This is most apparent at muscular attachments. Periosteal lesions of all degrees are prone to be complicated by hemorrhages due to the unyielding nature of the bone.

TEETH

In the teeth of adults with scurvy the dentin is seen to be resorbed and porotic. This process commences about Tomes's canals. The little replacement dentin that may be formed is inferior in appearance (osteodentin). In the pulp, chiefly about the vessels, atrophy, hyperemia, degeneration of the odontoblasts, the formation of small cysts and foci of calcification occur. The lesions develop first in the apex of the tooth and the bifurcation of the root canal. The fluid ground substance noted in experimental scurvy has also been observed in human material. The cementum is similarly affected.⁹

In the incisor teeth of the guinea pig early and extensive changes occur, because of the continuous rapid growth of these structures. In the guinea pig partial deficiency results in the formation of "osteodentin" and complete deficiency in undifferentiated matrix. In both cases the odontoblasts migrate from the predentin and revert to simpler types. Fish and Harris¹⁰ demonstrated defects in enamel and cementum as well as in dentin.¹¹

GINGIVA

Lesions of the gingiva occur only when teeth are present and are most severe about deformed or broken teeth. The gums become swollen and boggy and bleed easily. In severe cases of scurvy they have become so large as to hide the teeth and make mastication painful and difficult. Rarefaction of the alveolar bones results in loosening of the teeth. The gingival lesions commence on the papillae, first as a hyperemia with dilated, thin walled vessels with a tendency to intractable hemorrhage. Disintegration of the epithelium follows and infection with ulceration, granulations and even gangrene. Lesions in the mouth are remarkably constant. Indeed, fifty years ago scurvy was defined as a generalized, afebrile disease accompanied by symptoms of fatigue, hemorrhages, usually starting on the legs, and changes in the gums.

MUSCLES

In severe scurvy, now rarely seen except in experimental animals, severe changes occur in the muscles. Fragmentation of the striated fibers and intense reparative efforts marked by multiplication of the sarcolemma occur. If the scurvy is prolonged, replacement by connective tissue poor in collagen may be seen. Höjer considered these lesions plus metastatic calcification characteristic of scurvy but they have since been reported¹² in various other experimental deficiencies (although without the calcification which is by no means constant in scurvy). If such muscle changes are accompanied by spontaneous hemorrhages they would seem to constitute strong evidence of the pres-

9 Westin, G.: Ueber Zahnveränderungen in Fällen von Skorbut bei Homo, Stockholm, Fahlcrantz, 1931.

10 Fish, E. W., and Harris, L. J.: The Effects of Vitamin C Deficiency on Tooth Structure in Guinea Pigs, Brit. Dent. J. 58: 3 (Jan. 1) 1935.

11 The reader is referred to the report by Fish and Harris¹⁰ for a divergent interpretation of the pathogenesis of scurvy as well as for an excellent description of the lesions in the teeth of guinea pigs. The view of Fish and Harris, similar to that advocated by Höjer, is that the primary effect of deficiency is an atrophy of the parenchymal cells. In my opinion this theory fails to explain the phenomena or complete deprivation already referred to and applies only to the late, nonspecific effects.

ence of scurvy, especially in man, since typical lesions of the kind have been reported in human cases of scurvy but not, to our knowledge, in other instances of human avitaminoses.

EYES

In severe scurvy, bloody tumors of the conjunctiva and ecchymoses of the eyelids and elsewhere about the eyes may appear. The other eye lesions that have been reported in the past are now known to be the results of simultaneous vitamin A deficiency (degeneration of the cornea, pigmentation and night blindness).

SKIN

The skin is of particular interest because of the frequency of signs of the disease there and the clue such easily observable lesions give to the general status of the patient's vitamin C supply. The lesion of the skin that is characteristic of scurvy is the perifollicular or petechial hemorrhage. This is commonest on the lower extremities or wherever pressure exposes the weakness of the capillaries. In the epidemics of a hundred years ago much was made not only of the presence of the perifollicular hemorrhage but also of changes in the follicle itself,⁶ keratosis, dilated follicle mouth and fragmentation or loss of hair. Frequently dark, grayish pigmentation also was described. Identical observations were made during the World War.² As we now know, these were cases of combined deficiency of vitamins A and C. However, these observations raise the point whether similar perifollicular effects occur in uncomplicated scurvy, since it might otherwise seem that the presence of a diseased follicle, especially a thickened, hard one, would of itself predispose to hemorrhage. Undoubtedly similar lesions occur about normal hair follicles, as we have ourselves observed and other reports suggest, and have been absent in outspoken cases of vitamin A deficiency.¹³

OTHER LESIONS

Effusions, often blood stained, are common in the serous cavities. There may be slight edema about the ankles. Enlargement of the heart may occur. Circulatory collapse seems to have been a feature of the scurvy seen a hundred years ago and has been noted occasionally since. Whether there is a counterpart of the skeletal muscle lesions in the cardiac musculature, as Höjer believed, is doubtful. I have seen no such lesions, although fatty degeneration is common. Dilatation of the heart occurs. Atrophy of the bone marrow occurs in scurvy, and Wolbach¹² reports in experimental cases large areas of an amorphous material resembling amyloid. Except for this nothing characteristic has been reported, although the anemia of scurvy responds specifically to vitamin C.¹⁴ The gastrointestinal tract is largely spared. Minute hemorrhages may be found and even larger ones with secondary necrosis or ulceration (in experimental scurvy),¹⁵ but the study of human material does not support the view that the gastrointestinal tract suffers in a conspicuous fashion from vitamin C deficiency.

The adrenals atrophy in chronic scurvy as the absorption of cortical fat and vitamin C progresses.¹⁶ In

the early stages they are swollen and hyperemic. The presence of vitamin C in the adrenal cortex may be easily demonstrated by soaking the split organ in silver nitrate, a procedure which is useful in the autopsy room.

Atrophy of the lymphatic tissue and to a lesser extent of other organs, especially glands of internal secretion, occurs but seems due to the general effects of debility.

CORRELATION OF LESIONS AND VITAMIN SUPPLY

It would be of considerable value to determine the various levels of vitamin C deficiency associated with these morbid manifestations, and to a certain extent this may be done. It is known, for example, that the first morbid effect of a severe depletion is capillary fragility¹⁷ and probably also that the only morbid effect of a very slight negative vitamin C balance is capillary fragility or the presence of petechiae. Lind¹⁸ himself said of the petechiae that they are the most constant symptom of all and occur even in the mildest cases, that they may indeed be the sole symptom and that in such cases their presence is sufficient for the diagnosis of scurvy. All recent work has served but to confirm this view. In human scurvy these changes are preceded only by a short prodrome of from five to eight days of weakness and lassitude. Petechiae then, of skin or nose or other cavities, are the first morbid expression of vitamin C deficiency and are related to what has recently been spoken of as subclinical scurvy. In this condition capillary fragility is present. Chemical tests reveal a subnormal vitamin C concentration in fasting blood samples. A state of unsaturation is evinced by measurements of the blood concentration and urinary excretion after a test dose of ascorbic acid.¹⁹ The earliest stages of unsaturation are as a rule associated with morbid capillary resistance. Subclinical scurvy therefore appears to be definitely a pathologic state, albeit the deviation from health is slight. This degree of vitamin C deficiency is seldom recognized radiographically and with difficulty, if at all, by anatomic study. A comparable degree of deficiency in the guinea pig is uniformly associated with definite lesions in the incisors.

In moderately advanced scurvy the chemical tests reveal distinctly abnormal values and considerable vitamin C is required to saturate the patient. In such cases the hemorrhages may be large, commonly subcutaneous ecchymoses or hematomas. It is a general rule in scurvy that the more severe the disease the more extensive the hemorrhages and the more likely is hemorrhage from larger vessels. In this degree of deficiency skeletal lesions are present and will be found if the search is thorough. The study of Park and his colleagues gives us a clue to the relative efficiency of methods of diagnosis. Of eighteen cases of scurvy in young children only two were diagnosed clinically and only six at routine postmortem examination, yet all had distinct lesions.²⁰

In severe scurvy nearly complete unsaturation may be demonstrated by chemical tests. The initial doses

of vitamin, even when large, promptly are absorbed from the blood stream and little is lost in the urine. Hemorrhages are extensive and skeletal and gingival lesions outspoken.

CONCLUSIONS

It may safely be concluded therefore that the anatomic effects of vitamin C deficiency are very prompt to appear, certainly in the young, and that they occur, if the vascular changes are included, even in the mildest degrees of deficiency. Since clinical reports agree that subclinical scurvy, whether on the basis of chemical tests or measurements of capillary strength, is common, it may be assumed that morphologic stigmas due to the same deficiency are likewise common. However, both clinical and anatomic identification of scurvy remains, as it always has been, a matter of alertness on the part of the physician.

Finally, it may be pointed out that the recently acquired understanding of the scorbutic process affords pathologists and biologists a useful tool in the study of disturbances of intercellular materials. It should be of value also in the study of similar changes in senility.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

OHIO OROPHARYNGEAL CATHETER OUTFIT ACCEPTABLE

Manufacturer: Ohio Chemical and Manufacturing Company, Cleveland.

The Ohio Oropharyngeal Catheter is designed for the therapeutic administration of oxygen. It is a portable unit consisting of a multistage regulator with a gage of maximum pressure reading 3,000 pounds per square inch, a liter gage, a humidifier, one length of rubber tubing, a tapered nipple, one rubber nasal catheter, an adjustable wrench, a syringe for filling water jars, a tube of lubricating jelly and an adapter. The three wheel cylinder truck is optional. The multistage regulator has been approved by the Underwriters' Laboratories. It is supplied with screw connection fitting cylinders used for industrial purposes but may be adapted to tanks used for medical purposes. The humidifier consists of two water jars and a trap jar, so constructed that the oxygen passes through each in succession. A water level is indicated on the jars. The size of the water jars obviates frequent fillings. When higher rates of flow are used, the trap prevents water

Ohio Oropharyngeal
Catheter.

from passing into the tubing and hence into the patient's throat. The firm claims that the humidifier delivers a high concentration of oxygen, properly humidified, continuously over long periods of time.

The unit was investigated in a clinic acceptable to the Council and appeared to be satisfactory on the whole. However, the flow meter was not accurate for a small flow of 2 liters per minute. Of course, proper clinical use is guided by the patient's needs more than by the meter when flows under 6 liters per minute are used. For flows of 4 and 6 liters it was accurate.

Since the reducing valve and humidifier are satisfactory, the flow meter gage effective for most clinical purposes, and the rubber tubing of good nonkinking variety, the unit is considered satisfactory for clinical use.

In view of the foregoing report, the Council on Physical Therapy voted to include the Ohio Oropharyngeal Catheter Outfit for oxygen therapy in its list of accepted devices.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

- (1) NUTRADIET BARTLETT PEARS PACKED
IN WATER
- (2) NUTRADIET QUARTERED BARTLETT
PEARS PACKED IN WATER

Distributor.—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco.

Description.—Canned, peeled, halved and quartered Bartlett pears packed in water without added sugar.

Manufacture.—Bartlett pears are washed in hydrochloric acid to remove the residue of lead arsenate, which is used as a spray, are peeled by machinery and by hand, cut in halves or quarters, and the cores and stems are removed. The fruit is soaked in a 3 per cent salt solution, rinsed in running water and packed in cans. Water is added and the cans are heated to 71 C. for six minutes in the presence of steam, sealed and processed for twelve minutes in boiling water.

Analysis (submitted by manufacturer).—Moisture 90.3%, total solids 9.7%, ash 0.16%, fat (ether extract) 0.07%, protein (N \times 6.25) 0.2%, crude fiber 0.6%, carbohydrates other than crude fiber (by difference) 8.5%, titratable acidity as citric malic acid 0.2%.

Calories.—0.35 per gram; 10 per ounce.

Claims of Manufacturer.—For diets in which sweetened fruit is proscribed.

MRS. PALEY'S BABY FOOD—STRAINED MIXED VEGETABLES WITH SOYA BEAN, DICAL- CIUM PHOSPHATE AND WHEAT GERM

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—A combination of cooked vegetables including carrots, potatoes, celery, tomato purée, cabbage, soya beans, wheat germ, onions and added dicalcium phosphate.

Manufacture.—The vegetables are prepared as for Mrs. Paley's Baby Food—Strained Vegetable Soup with Beef Broth and Cereal (THE JOURNAL, Sept. 17, 1938, p. 1101). Wheat germ is pressure cooked with the prepared vegetables in formula proportions, and definite amounts of dicalcium phosphate are added. The mixture is sieved, filled into jars, vacuum sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 81.5%, total solids 18.5%, ash 1.5%, fat (ether extract) 0.8%, protein (N \times 6.25) 4.4%, reducing sugars as dextrose 0.5%, sucrose 1.1%, crude fiber 1.1%, total carbohydrates other than crude fiber (by difference) 10.7%, calcium (Ca) 0.246%, phosphorus (P) 0.137%, iron (Fe) 0.003%.

Calories.—0.7 per gram; 20 per ounce.

DEXTROSE, KARO BRAND

Manufacturer.—Corn Products Refining Company, New York.

Description.—U. S. P. dextrose.

Manufacture.—Raw kernels of corn are softened by steeping in a warm bath containing a small amount of sulfur dioxide. The starch, separated from the other constituents, is hydrolyzed with hydrochloric acid and the resulting liquor is filtered, clarified, concentrated and crystallized. The first yield is recrystallized from water. The method of manufacture is covered by patents numbered 1508569 and 1559176.

Analysis.—Ash 0.096%; moisture 7.87%; optical activity + 52.63°; chlorides, trace; starch, absent; erythrodextrin, trace.

Calories.—3.7 per gram; 104 per ounce.

SATURDAY, OCTOBER 8, 1938

THE EXPERIMENTAL PRODUCTION OF OVULATION

Periodically a graafian follicle ripens and ruptures, and the ovum escapes. The ruptured follicle then develops into a corpus luteum, a gland of internal secretion which is necessary for the implantation of the fertilized ovum. These brief facts barely outline the immensely complicated story of ovulation. No one has actually seen a graafian follicle rupture nor has any one heretofore succeeded in producing ovulation in women. Theoretically, the ideal substances for this purpose would be certain extracts of the anterior lobe of the pituitary gland, but these have not been available in a sufficient state of purity. Gonadotropic substances derived from the urine and blood of pregnancy have failed to produce any consistent changes in ovarian activity when given parenterally.

Recently a gonadotropic substance has been found in the serum of pregnant mares and sufficiently purified, it is thought, to bring about ovulation in women. This substance was first observed by Cole and Hart¹ in 1930 in high concentration in the serum of pregnant mares. Experiments have shown that its action closely resembles that of pituitary extracts. It produces ovulation, luteinization and follicle stimulation. It is not soluble in the usual fat solvents used for the isolation of estrogenic substance. A highly purified preparation of this gonad-stimulating principle was prepared by Cartland and Nelson,² and biologically assayed.

Some unusual observations of the effects of this substance have been made by Davis and Koff³ at the University of Chicago and the Chicago Lying-In Hospital. After preliminary experimental work with this

gonadotropic fraction obtained from the serum of pregnant mares, they administered it intravenously to thirty-six women who were awaiting abdominal operations for a variety of pathologic conditions. These women were first carefully tested for protein sensitization. They were mostly at the period of life when there is a rapid decrease of activity of the ovaries; others in the group were suffering from pathologic conditions which would mask any results that might be obtained. The gonadotropic substance was given intravenously on varying days of the menstrual cycle; then the ovaries of these women were observed later when they came to undergo laparotomies.

It was observed that ovulation had occurred recently in about half of the women to whom this substance had been given. The evidence was obtained not merely by gross inspection of the ruptured follicles but also by microscopic examination. The studies made of these ovaries revealed corpora lutea present in earlier stages than had ever before been described. Careful comparison indicated that most of these corpora lutea were less than eighteen hours old and well within the time that elapsed between the administration of the gonadotropic substance and the time the ovary was removed. It has been considered heretofore that the process of ovulation in the human being extended over a period of several days or longer. The time that elapsed from the administration of the gonadotropic substance until ovulation in these patients was unusually short. The authors² believe that this substance is capable of causing rapid follicle growth; apparently, under this influence, the follicles ripen, rupture, release their ova and are converted into corpora lutea all within twenty-four to thirty-six hours.

The clinical application of this experimental work presents problems. The significance of some of the observations is not well understood. Heretofore the clinical administration of gonadotropic substances has met with little success. Now, however, an abundant source of supply and a highly purified product are available. Biologically this gonadotropic substance resembles extracts and implants of the anterior lobe of the pituitary. It differs biologically and chemically from all other gonadotropic substances studied. Unlike the gonadotropic substance in the blood and urine of pregnant women, the fraction from mare serum is not excreted in the urine at any time during gestation; unlike substances derived from the urine of pregnancy, it is not filtrable through collodion membranes. Mare serum hormone apparently is a peptide.

Much more experimental work is necessary before the clinical application of this product can be adequately defined. Its use under very carefully supervised conditions may prove to be efficacious, however, in the treatment of patients in whom ovulation and follicle growth are at fault.

ARTHRANOL—ANOTHER "CURE" FOR ARTHRITIS

The greater the number of persons with a certain disease, the greater the number of remedies offered for treatment. One of the most lucrative of all fields is arthritis. The results of treatment of arthritis and rheumatism are easily susceptible to misinterpretation; the condition is subject to numerous remissions and relapses. Small wonder, then, that as many products are offered for sale with little or no evidence of their usefulness. Frequently products for the treatment of arthritis are exploited indirectly to the public by newspaper and periodical publicity planned to follow the presentation of a paper at some scientific gathering. The ridiculously optimistic claims advanced by Seydel for a benzoate type of product called Subenon were widely publicized after the meeting of the American Chemical Society two years ago. To the credit of the American Chemical Society, it promptly took effective action to prevent repetition of such impositions in the future. More recently other manufacturers have attempted to exploit the profession and the public with promotion of high potency vitamin preparations and various colloidal preparations for use in "rheumatism." The patient with arthritis grasps at every straw in the hope that long treatment may be avoided—that at last some specific method has been discovered whereby he may recover full health and vigor. Naturally any announcement that such a startling discovery has been made appeals to a large proportion of the public. The premature release of misinformation does harm.

The current example of such unwarranted exploitation in the field of medicine is "Arthranol." The product has been available for about three years. In *Time*, September 26, appeared the statement:

Last week at a meeting of the Atlantic County Medical Society, 60 year old Dr. Samuel Stern of Atlantic City announced that he had successfully used a new drug, Arthranol, for the treatment of arthritis. Arthranol is a highly complex salt made from a nitrogen compound, phosphorus and iodine.

When such announcements are published, the effects are promptly felt in the offices of the American Medical Association. Physicians and laymen alike inquire concerning the composition of Arthranol and seek opinion of its value. This product is marketed by the Atlantic Research Foundation, whose president and director is Dr. Stern. In 1936 the Council on Pharmacy and Chemistry was informed that the foundation was established as a nonprofit organization to provide the proper handling of products, all income to be devoted to further medical research. It was also stated that the foundation has charged a fee of \$3 for each box of Arthranol. An announcement appeared in 1936 in the lay publication *Modern Mechanics & Inventions Magazine* that "arthritis and rheumatism, two of humanity's most common afflictions, are now believed to be under control as the result of a new serum developed by

Dr. Samuel Stern of Atlantic City, N. J., and William Kurland, chemist." There was also a picture of Dr. Stern and William Kurland standing in front of a laboratory desk overcrowded with microscopes and other chemical apparatus. It was stated that the serum has proved successful in 97 per cent of 125 cases. Now, two and one-half years later, Dr. Stern states, according to *Time*, that Arthranol¹ has been given to practically twice the number of patients (250) and that 90 per cent of these patients were relieved. Maybe if one were to extrapolate a curve for 1,000 patients, the number of "relieved" would be less than 48 per cent, as the later report indicates the product was less effective in the next 125 patients!—all of which goes to show that the figures may mean little. In reply to a request for information in 1936, Dr. Stern stated: "The new chemical compound consists of ammonia, 26.1 per cent, phosphorous 4.7 per cent, and iodine 69.2 per cent." This statement, of course, was entirely inadequate. He also wrote: "It is administered hypodermically 1 cc. to a dose in buffered isotonic solution. We have tried Locke, Ringer and other menstra, and at present we are using a 5 per cent dextrose with $\frac{1}{4}$ per cent chloretone as a menstra, having found it is less painful and probably more efficient than the other menstra we have previously used. As to literature, reports etc., no reports have been made to date as we are still collecting data and pursuing our researches." Last week an inquiry was telegraphed to Dr. Stern asking again about the composition of the product and about the literature. In the circular that accompanied Dr. Stern's reply the product was described as "amino-phospho salicyl, Benzoyl, iodide." Dr. Stern gave the following composition for the product:

| Average Analysis of Arthranol Per Cent | | |
|--|--|----------|
| Total ammonia..... | (NH ₃) | 15.02071 |
| Ammonium phosphate di-basic..... | (NH ₄) ₂ HPO ₄ | 24.9165 |
| Ammonium iodide..... | (NH ₄)I | 3.1887 |
| Ammonium chloride..... | (NH ₄ Cl) | 9.7030 |
| Ammonium benzoate..... | (C ₆ H ₅ .CO.O.NH ₄) | 32.5290 |
| Ammonium salicylate..... | (C ₆ H ₄ (OH).CO.O.NH ₄) | 20.0390 |
| Water | | 9.0000 |

The fourth decimal point for such "average" figures is not significant.

The statement of composition indicates that there is nothing wonderful in the preparation; the product apparently is not of the same composition as that stated in 1936. The largest component seems to be ammonium benzoate, which years ago was generally discarded in the treatment of "rheumatism" in favor of the more valuable salicylates. Over half the mixture, according to the information given, consists of ammonium benzoate and ammonium salicylate. Alkali iodide, another ingredient, has been used for years in certain forms of arthritis. The composition of Arthranol does not warrant the optimistic claims made for it. All the active ingredients have, in fact, been employed many times before.

1. Also spelled Arthronol.

Rather naively Dr. Stern further states:

Now, as to literature at this writing I have none except a mimeograph sheet of instructions for the use of our remedy which I am enclosing. I am in hopes to receive from the printer shortly reprints of the paper I presented before the Atlantic County Medical Society. I am taking this step in having reprints made in advance of the publication of this article in order to supply the immediate demands for an accurate knowledge of the claims I am making.

Please understand that we are most willing and anxious to give any information whatsoever that you or the profession may desire.

Our research laboratories are straining every effort to supply the demand of this article but I fear it will be impossible. I am endeavoring to license a responsible manufacturer to produce this product, of course, it shall be upon strictly proper and ethical lines. I am in hopes to be able to complete this very shortly, in the mean time, I will strain every point to meet the demands that are being made upon me.

This is not the first time such publicity has been attached to Dr. Stern. A clipping from the *New York City Telegram*, Nov. 10, 1923, states:

New Diabetes Treatment

Atlantic City, Saturday.—A new treatment for diabetes and acidosis, in the form of a cream, which it is claimed can be applied externally and absorbed to neutralize poisonous acids was announced by Dr. Samuel Stern of this city, speaking before the Atlantic County Medical Society.

Today no one hears of his treatment for diabetes; fifteen years hence will any one hear of Arthranol?

Current Comment

YELLOW FEVER VIRUS IN JUNGLE MOSQUITOES

In 1935 THE JOURNAL called attention¹ to the important implications resulting from the investigation of yellow fever in the Valle do Chanaan, Esperito Santo, Brazil. In this strictly rural epidemic *Aedes aegypti* mosquitoes were not found but many other insects were present and the epidemiologic evidence pointed to some other vector or vectors. Since that time more than twenty similar outbreaks have been observed in various parts of South America which have demonstrated that man is generally infected only while in contact with the forest or jungle. Household infections, in fact, have been uncommon except when the house stands within the jungle. It has been shown, furthermore, that a number of Brazilian mosquitoes other than *Aedes aegypti* can become infected under laboratory conditions, but successful transmission by bite has been obtained with only three species: *Aedes scapularis*, *Aedes fluviatilis* and *Haemagogus capricorni*. The 1938 outbreak of jungle yellow fever in the state of Rio de Janeiro, Brazil, afforded an opportunity actually to demonstrate the presence of yellow fever virus in mosquitoes caught in the jungle.² More than 24,000 mosquitoes were sent in over a period of eleven weeks. Positive results with monkeys and mouse protection tests were obtained with *Aedes leucocelaenus*, *Haema-*

gogus capricorni and one or more as yet unidentified species of sabethine mosquitoes. The evidence presented thus incriminates two species of forest inhabiting mosquitoes, *Aedes leucocelaenus* and *Haemagogus capricorni*, as natural vectors of yellow fever and indicates that one or more species of sabethine mosquitoes may harbor the virus of the disease, although the latter have not been definitely implicated in actual transmission. Thus, while there is little reason to believe that *Aedes aegypti* is not usually the most important vector of yellow fever, the identification of other natural mosquito vectors has enormously complicated the problem of yellow fever control.

DOCTORS AND LAWYERS

Editorially the *San Francisco Chronicle* said recently:

The State Board of Medical Examiners announces that 172 of 174 applicants had passed the examination for physicians and surgeons recently held in San Francisco. Only two fell short of the high grade of 75 per cent required, and these two would doubtless have met any less stringent standard. On the same day, eleven out of fourteen met the requirements for the much more limited art of chiropody.

There has never been an examination for admission to the bar of California, since the present examination system was established, on which anything approaching this proportion of success was reached. It would be a rare examination which even half of the applicants passed.

And this is not because the standards for lawyers are higher than those for physicians, or the examinations more difficult. The exact contrary is the case. If the preliminary training of aspirants to the bar were uniformly as high as that in medicine, most of the candidates would pass, too. In fact, nearly all of those who have this training do pass.

The difference is that there are now no medical schools but class A schools; they admit none but highly selected university graduates, and they permit only those to remain in medical school who show the necessary ability and diligence. Naturally, the survivors of this process pass the state examinations also, with few or no exceptions.

If the law is ever to be in fact what it has always been in name, a "learned" profession, the same standards of preparation will have to be required of aspirants to it. The question still remains whether the law should be a learned profession. Curiously enough, there are two opinions in this. There is only one, as to medicine.

This comment indicates and emphasizes the necessity for an objective, unbiased grading of professional schools. A single state board could not possibly undertake the examination and rating of such schools, for the boards have neither funds nor trained personnel. Associations of professional schools could not assume the responsibility for self appraisal because the schools cannot escape being motivated by self interest. In medicine the medical profession itself, through the Council on Medical Education and Hospitals, has provided an independent yet dependable classification which has won the support of public opinion and thereby gained all but universal acceptance. In the field of legal education there has been much improvement as a result of the efforts of the American Bar Association, but a truly satisfactory standard will not be attained as long as the people themselves are undecided as to whether the law is, or is not, a learned profession.

ORGANIZATION SECTION

AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE

Walker County, Alabama

Proceeding with the plan to present some of the reports from county medical societies throughout the country, the information on the Summary Sheet and the accompanying comments for Walker County, Ala., are given.

Walker County has a population of 65,000, of which a little over 5,000 live in the city of Jasper. Forty-three forms were sent out to physicians and dentists, of which seventeen were returned. In addition to physicians and dentists two hospitals located in the county, the nurses' organization and the health department all contributed information to the Survey, as did one additional organization.

There are thirty-five physicians in active practice, and the greatest distance that the nearest physician would have to travel to reach persons in the area was 15 miles. There were four full-time and three part-time nurses, twelve pharmacists and two hospitals, both of which were general hospitals. There were twenty private rooms, twenty semiprivate rooms and sixty-four wards in the hospitals. During 1937 22.5 per cent of the private rooms were occupied, 10 per cent of the semiprivate rooms and 30 per cent of the ward beds. The charges in the hospitals varied from \$5 to \$6 a day for accommodations in private rooms, \$3.50 in semiprivate rooms and from \$2 to \$2.50 in wards.

Five outpatient departments or clinics were operated, one by a hospital and four by health departments. In addition, the Kiwanis Club provided for between eighty and 100 tonsillectomies in a special clinic.

All medical services in the schools in the neighborhood are supervised by the health department with one exception, where another agency is responsible for such supervision. Medical service in the schools is confined almost exclusively to examinations.

There are seventeen plant arrangements for medical service. Practically all the coal mines and the lumber operators have contract schemes providing ordinary medical care at a cost of from \$1 to \$1.50 a month and hospitalization for the entire family for an equal additional sum. This covers about 13,000 persons.

The seventeen physicians who returned the forms reported that they had given free services to 1,282 persons during 1937, and the dentists reported seventy-five who had been given dental care without charge. In addition, 487 hours was given by physicians to the care of free ambulatory patients in outpatient departments, dispensaries or clinics. Of the hospital patients, 1,727 were classified as pay and part pay, 394 as public charges and sixteen as free patients. The public charges received 2,670 days of hospital care and the free patients 161 days. Visits by 189 patients to outpatient departments, clinics and dispensaries totaled 252 during 1937. Pharmacists reported that they had compounded 387 prescriptions for which no charge was made and 600 at cost or reduced fees.

The ability or inability of patients to pay was determined by the Department of Public Welfare, and the funds for the medical care of the indigent were provided by the city or county.

No patients who needed hospital care were denied admission or turned away from outpatient departments, and the nurses reported that there was no one in need of medical service which it was found impossible to secure. The Health Department, however, reported that 150 persons requested medical care which could not be furnished owing to lack of funds. In reply to the question as to the "Total number of persons, during 1937 . . . who were unable to obtain either medical, dental, nursing or hospital care" it was stated that "No definite number reported by any physician, but there were probably several hundred."

One per cent of the births were unattended by a physician or midwife, and 98 per cent of those born alive were immunized against diphtheria. Forty-two per cent of the obstetric patients waited until after the third month before consulting a physician.

There was a birth rate of 25.5, a death rate of 7.4 and a maternal mortality rate of 6 per thousand. There was a diphtheria morbidity rate of 2.3 per thousand and an infant mortality rate of 35 per thousand. Three of five pharmacists reported that there was a decrease between 1936 and 1937 in the number of sales of home remedies or "patent" or proprietary remedies as compared with physicians' prescriptions.

Some of the comments which accompany the report were as follows:

It is clearly the opinion of all the medical and dental groups that there should be no complete federal or state control of the practice of medicine as a whole. Many express the opinion that there should be some form of government aid for the medical care to those who are already on the relief agency rolls and being furnished money for food and clothing. The majority opinion seems that whatever aid is offered should be furnished through the county units with the plan to be cooperative between the department of public welfare and the county medical society. Further opinion is advanced that the state government should offer some plan of hospitalization for the indigent in the private hospitals of the state, rather than in a large state charity hospital or hospitals.

(Comment: A hospitalization plan of this type would place many of the indigent who need medical care in the small community hospitals of the state where doctors serving on the staff could furnish medical and surgical attention free of charge and with but little expense to themselves.)

Believe medical society should have a fund which should be administered by the society to needy as approved by the Department of Public Welfare.

A setup should be made so that a person who is indigent could have medical care and medicine on the recommendation of the welfare worker and physician. The pharmacist and physician both should have their regular fee.

All coal mines and most lumber operations in this county have a contract physician. With the exception of one company employing 450 men, each employee contributes \$0.75 or \$1 for a single man, with an additional \$0.50 for the family and dependents. This covers ordinary medical care and medicines such as aspirin, quinine, cathartics, cold mixtures, and like inexpensive medicines.

The one exception does not make the men contribute, but no medicine is furnished and calls are not made more than 2 miles from the office.

At some of the mines \$1 per worker is paid to the hospital and ward service, operation and hospitalization are furnished. This includes x-ray. Does not include serums, vaccines, etc. Includes family.

One mine has mutual benefit run by U. M. W. A. \$1.50 per month, free choice of physician, limited choice of hospital. Does not include cancer, i. e., breaking law; maternity (hospital only in emergency operative cases). Also takes care of burial.

One mine has same setup but at less rate and is always behind. Seventy-five per month.

Alabama group hospitalization also operates in area.

Prowers, Kiowa and Baca Counties, Colorado

The return of Summary Sheets from various county medical societies which have completed their phase of the work in the Study of Medical Care makes it possible to give short reports by counties based on their recorded data. The following information and comments are taken from the Summary Sheets and attached comments returned by the Prowers County Medical Society.

Prowers County Medical Society includes Prowers, Kiowa and Baca Counties, which are all located in the southeastern corner of Colorado. The three counties combined have an area of 5,980 square miles and a population of 23,700. Practically the entire population is engaged in farming except for the 4,233 persons in Lamar, the county seat of Prowers County, and the people in the smaller towns scattered throughout the counties.

In 1937 there were seventeen physicians in active practice, six dentists, two full time private nurses, one part time private nurse, two full time public health nurses and four pharmacists. The greatest distance the nearest physician would have to travel to reach persons in this area was 35 miles. There is only one general hospital, located at Lamar, and it has a total of forty-one beds.

Forms were sent to twenty-two physicians and dentists, and nine were returned; the hospital did not return its form, and only one nurse returned a form. Reports were received from one health department, three relief agencies, six schools, four pharmacists, and the Red Cross and American Legion. Two private agencies and one governmental agency arrange for or provide medical services. All three of them provide hospitalization, drugs, eye glasses and surgical appliances, and one provides care in the physician's or dentist's office and one in the home. Of the six schools below college which answered the forms, three have only inspection and three give examinations, but none of them provide any medical treatment. There are no colleges in this area. Medical services for special groups are provided by the State Antituberculosis Association and the State Aid to Crippled Children.

The physicians who reported estimated that they had provided 2,130 persons with free medical care and the dentists 235 persons with free dental care. No patients

were referred to the hospital for free care and only thirteen made direct application for such care. The total number of pay and part pay patients in the hospital in 1937 was 399, public charges 243, free thirteen. The total patient days of hospital care was 5,032. Of this, pay or part pay patients received 2,564 days, public charges 2,349 days, free patients 119 days. The pharmacists compounded fifty free prescriptions and 100 or more at cost or reduced prices.

The relief agencies provide medical care for the indigent. Welfare workers determine the indigence of the persons applying for such care. Funds to pay for medical care come from the county, state and federal governments for the county relief agencies. Two private philanthropic agencies, the Red Cross and the American Legion, provide funds for some medical care also.

The report states that no patient in need of hospital care failed to receive such care. The nurse reported that no person visited by her was not receiving medical care. Two thousand persons made requests for medical care from the health departments and received it in every case. The welfare and relief agencies reported that medical care was furnished to all persons needing it. However, there were 657 pupils in the schools who needed medical care and of these 238 did not receive it because of financial reasons or indifference.

All the physicians who took part in the study were active in performing preventive medical services in private practice as well as for the public health departments. Sixty per cent of the children who entered school for the first time in 1937 were successfully vaccinated against smallpox, but very few of the children born in 1937 were immunized against diphtheria.

With regard to the number of sales of medicine on physicians' prescriptions for the year 1937 as compared to 1936 in relation to the number of sales of home remedies or "patent" or proprietary remedies, three pharmacists reported an increase and one reported a decrease in sales of medicine on physicians' prescriptions.

In general the comments which accompanied the Summary Sheet express the opinion that no person who needed and requested medical care failed to obtain such care but that medical care should be made more easily available to people in the rural areas. Some of the comments were as follows:

FROM SCHOOLS

1. No adequate program of health is functioning in our schools.

4. I feel that our Health Program is not sufficient. In many cases the children needing help are financially unable to see a doctor or dentist. I believe the school or county should have a doctor or dentist to take care of children when they are in need.

FROM COUNTY NURSE

At the present time our local doctors are ably caring for the indigent sick, through local arrangements with the County and Bureau of Public Welfare and their own contributions of their time, service and supplies used in the care of the indigent. In the dry land section of our county are 672 dry land farms. These people live some as far as 35 miles from a doctor and hospital. Many are very poor and do not seek medical care until a late date. These ten doctors in the county supply an area covering 1,043,200 acres. Six of these doctors are located in the city of Lamar; the other four, some of which live in small towns, reside about 25 miles from Lamar. The need is to reach the expectant

mother, the mother with the infant and small children, with nutritional problems. Sanitation: the care for tuberculosis patients and the contacts, the need for corrections of physical defects in the children is ever present, and keeps a public health nurse ever anxious for adequate medical care.

FROM WELFARE DEPARTMENTS

The need for medical care in this county seems to be more acute than in some neighboring counties. This may be due to several causes such as continued extreme drought and dust, possible former malnutrition of children, etc. This is evidenced by the fact that approximately 30 per cent of all relief costs in this county are used for medical and hospitalization purposes. We believe that a close cooperation between the county medical society, the department of public welfare and the state department of public health is necessary in order to somewhere near adequately care for the health of indigent residents. We have

observed that, in the local area where county physicians are changed every two months, unsatisfactory situations occasionally develop. We would recommend consideration of some plan which would provide that indigent medical patients could have their choice of physicians.

FROM AMERICAN LEGION

Medical care well supplied by present methods.

FROM RED CROSS

We believe all needs are well taken care of under present arrangements.

FROM PHARMACISTS

I believe there should be provisions made for county or districts of two or three counties, clinics available to indigents and people of low incomes.

I believe the present county relief is satisfactory.

WOMAN'S AUXILIARY

Colorado

The auxiliary to the State Medical Society of Colorado held its annual meeting at the Stanley Hotel, Estes Park, September 8-10. Frederic H. Douglas, curator of Indian art, Denver Art Museum, was speaker at the dinner on Thursday evening September 8. Dr. John W. Ames of Denver was speaker at the joint banquet and dance of the medical society and auxiliary September 10.

The auxiliary to the Denver Medical Society held its annual theater party at Elitch's June 26 for the purpose of raising funds for the work of the auxiliary. The net proceeds were \$465.

Indiana

The auxiliary to the Indiana State Medical Association held its annual meeting at the Murat Temple, Indianapolis, October 4-6. Dr. Norman M. Beatty, chairman of the Committee on Public Policy and Legislation of the Indiana State Medical Association, was the speaker at the annual auxiliary breakfast October 5.

The Indiana auxiliary published its first edition of the *Hoosier News-Letter* about October 1. Mrs. W. F. Hughes, 4025 North Meridian Street, Indianapolis, is its editor.

Kentucky

The sixteenth annual meeting of the auxiliary to the Kentucky State Medical Association was held in Louisville October 3-6. Speakers at the annual luncheon were Mrs. Charles C. Tomlinson, president of the Auxiliary to the American Medical Association, Mrs. Luther Bach, president of the Auxiliary to the Southern Medical Association and Drs. Horace G. Reynolds, William E. Gardner, Virgil Kinnaird, Arthur T. McCormack, and Van A. Stille. During the convention a study class was held on Eye Conservation and Prevention of Blindness.

Louisiana

Mrs. Frederick G. Ellis of Shreveport is president and Mrs. S. M. Blackshear of New Orleans is president-elect to the auxiliary to the Louisiana State Medical Society for 1938-1939.

The Shreveport Medical Association entertained its auxiliary with a dinner at the Shrine Club at Cross Lake August 9. Drs. Paul D. Abramson and Robert Lucas were speakers. Special guests were Mayor and Mrs. Sam S. Caldwell. More than eighty physicians and their wives attended the meeting.

Michigan

During the past year the Battle Creek auxiliary provided maternity kits for about 500 indigent mothers and is now making plans to furnish a room in the new community hospital.

The auxiliary to the Kalamazoo Medical Society provided a Fairchild hearing aid for the use of children in the hard of hearing department in the public schools. The auxiliary has assisted the Grand Rapids Medical Society in providing a benevolent fund to be used for members and their dependents in distress.

Oregon

The Multnomah County auxiliary enrolled thirty-three new members since the beginning of the fiscal year up to August 1938. Members of this auxiliary have knitted sweaters and purchased four dozen sun suits for the children at the Albertina Kerr Nursery. This auxiliary has made eleven loans this year to students in the junior and senior years at the University of Oregon Medical School, all made on recommendations of members of the faculty. The auxiliary sponsored a "Doctor's Hobby Show" for the last week in September, and as early as August forty-six doctors had requested space for exhibits. The Benton County auxiliary has collected instruments and equipment which belonged to various pioneer physicians and placed them in the Oregon State College Museum. This county auxiliary has also placed *Hygeia* in many of the rural schools. The Coos-Curry Counties Woman's Auxiliary has adopted the County Farm as the project to which their interest is to be devoted in providing entertainment for the inmates. Members of the Klamath-Lake County auxiliary, have provided thirty quarts of canned fruit and several dozen glasses of jelly to the WPA nursery school. During the Nurses' state convention this auxiliary held a tea for the nurses at the home of Mrs. E. D. Johnson.

Virginia

The sixteenth annual meeting of the auxiliary to the Medical Society of Virginia was held at Hotel Danville, Danville, October 4-6. Mrs. James B. Stone of Richmond is president and Mrs. Hawes Campbell of Venter is president-elect. Speakers at the annual luncheon were Drs. G. F. Simpson, president, and Alex F. Robertson, president-elect, of the Medical Society of Virginia, P. W. Miles, president of the Danville-Pittsylvania County Medical Society and P. St. L. Moncure, chairman of the advisory council to the auxiliary.

The auxiliary to the Norfolk County Medical Society realized \$377.39 from three entertainments at the Norfolk Yacht and Country Club during the year. The proceeds were given to a patient at the Tidewater Memorial Hospital and used for other philanthropic work.

Members of the auxiliary had charge of booths during the drive for funds for the American Society for the Control of Cancer. The auxiliary contributed ten cents from its treasury for each active member to the Jane Todd Crawford Memorial.

The Accomac-Northampton auxiliary held a social meeting July 5 at the Accomac Country Club. Members of the medical societies of both counties and nurses from the Accomac-Northampton Hospital were guests of the auxiliary.

The auxiliary to the Williamsburg-James City County Medical Society held a program on health June 27 at the home of Mrs. W. L. L. Smoot. The importance of a yearly physical examination for every individual was emphasized.

Wisconsin

An auxiliary to the LaCrosse County Medical Society has recently been organized under the direction of Mrs. Eben J. Carey, state organization chairman.

MEDICAL ECONOMIC ABSTRACTS

COMPARISONS OF INFANT MORTALITY

Scientific comparisons of vital statistics from different nations are notoriously difficult. Differences in economic, climatic, racial and general social environment, as well as in statistical methods, are so great in quantity and diverse in quality as to make all conclusions based on such comparisons subject to a wide margin of error. Since constantly repeated comparisons of infant mortality disregard all these distorting elements, it may assist a fairer conclusion if an effort is made to eliminate some of the misleading factors.

The population of the United States is a mixture of nearly all races. Some of the most important racial ingredients have a high infant mortality in their native countries; nearly one tenth of the population is composed of Negroes—often with an infant death rate twice as high as that of the white population. Sectional differences in infant mortality rates are greater than in almost any other country. Comparisons of absolute rates at any given period exaggerate nearly all these errors more than comparisons of the rate of change in mortality. This is peculiarly significant when considering the effects of any efforts to reduce infant mortality. Comparisons of rate of change may be equally misleading unless the points of

parable in climate, racial characteristics and general social conditions with the European nations listed in table 1.

The large Negro population in some of these states tends to make this comparison unfavorable to the United States. However, standards of living average higher here than in some of the European nations listed.

No attempt is made to allow for errors in registration of either births or deaths, although these are often significant.¹

These figures would seem to indicate not only that in the states listed the rate was on the average lower in 1920 but that in spite of this handicap the death rate declined more rapidly in the United States than in Europe. At the present time the rate of infant mortality is lower in these sections of the United States than in those European nations in which conditions are most nearly comparable.

"INDEMNITY INSURANCE"

The House of Delegates of the American Medical Association at its recent special session approved "cash indemnity insurance" as a method of paying medical costs. Unthinking exponents of socialized medicine may endeavor to twist this approval into a reversal of policy. There are, however, basic differences in the most vital points of the two systems.

Practically no one—and certainly not the American Medical Association—has ever opposed the payment of medical bills through insurance. The medical profession has objected most strenuously and continues to object to the compulsory wholesale purchase and retailing of medical service to patients by an insurance company, government agency, or any other organization or individual. This objection rests on the proof afforded by vital statistics that during this process of purchase and retailing the medical service is adulterated by politics and depreciated by administrators until it loses much of its value as a protection of the public against disease and death.

Sickness insurance in most countries arose out of systems of contract practice, the administrators of which wished to keep control of the medical service. Politicians were quick to see that service benefits could be sold to voters unable to judge their value for greater political assets than could cash benefits. In the most commonly advocated plans of voluntary and compulsory sickness insurance, premiums are collected in cash and then transformed within the insurance administration into service benefits for the insured. All other systems of insurance collect premiums and pay benefits in the medium of exchange. The two sides of the balance sheet are then written in the same units. It is much more difficult to tamper with the book-keeping for political purposes or to deceive the sick as to the benefits received than in systems in which receipts are counted in cash and benefits are delivered in an unmeasurable service. Indemnity insurance collects the premiums in cash and pays cash to the insured on a definite scale in accordance with the economic losses suffered from sickness.

There would be fewer complications and far less red tape in such an indemnity system than in one with service benefits. Free choice of physician would be automatic. Restrictions on prescribing and other phases of treatment would be unnecessary, as there would be no need to deceive the patient as to the quality and extent of the service he was receiving.

This is not a proposal for an untried experiment. Such a system is in almost universal use by commercial insurance companies. It has been introduced with success into some industrial plans. It is the plan on which old-age, unemployment, and all other forms of social insurance are conducted. There is a decided trend in this direction in even the compulsory systems, as shown by certain features of the French and Swedish sickness insurance plans; both of these, however, are still more or less hybrids of the indemnity and service systems. They retain so many of the evils of the latter, aside from their governmental, compulsory feature, that they cannot be offered as patterns to follow.

TABLE 1.—Infant Mortality
(Deaths of children under one year per thousand live births)

| Countries | 1920 | 1935* | Per Cent of Decline |
|-------------------|------|-------|---------------------|
| Austria | 157 | 100 | 36 |
| Belgium† | 104 | 85 | 18 |
| Canada‡ | 102‡ | 71 | 30 |
| Denmark | 90 | 71 | 21 |
| England and Wales | 80 | 57 | 29 |
| France | 99 | 69 | 30 |
| Germany | 130 | 68 | 48 |
| Italy§ | 127 | 101 | 20 |
| Netherlands | 73 | 40 | 45 |
| Scotland | 92 | 77 | 16 |
| Sweden | 63 | 47 | 25 |
| Switzerland | 84 | 48 | 43 |
| United States§ | 86 | 56 | 35 |

* Preliminary figures.

† Previous to 1934, infants born alive but who died almost immediately after birth are not included.

‡ Registration population, slightly smaller than the total population.

§ Rate for 1920 not given; 102 is the rate shown for 1921.

¶ From 1921, the rates relate to the present area.

§ Birth registration area (59.8 per cent of total population in 1920 and 100 per cent since 1933).

TABLE 2.—Infant Mortality
(Deaths, exclusive of stillbirths, under 1 year of age per thousand live births)

| State | 1920 | 1935 | Per Cent of Decline |
|---------------|-------|------|---------------------|
| Iowa | 54.9* | 47.1 | 14 |
| Massachusetts | 90.9 | 48.3 | 47 |
| Minnesota | 66.4 | 44.7 | 33 |
| Nebraska | 64.2 | 41.2 | 36 |
| New Hampshire | 88.0 | 53.9 | 39 |
| New Jersey | 74.1† | 46.2 | 38 |
| New York | 86.3 | 48.0 | 44 |
| Oregon | 61.8 | 41.2 | 33 |
| Rhode Island | 92.7‡ | 47.2 | 49 |
| Washington | 66.4 | 45.2 | 32 |
| Wisconsin | 76.5 | 46.0 | 40 |

* Rate for 1924, first year Iowa was included in birth registration area.

† Rate for 1921, first year New Jersey was included in birth registration area.

‡ Rate for 1921, Rhode Island was dropped from registration area in 1919 and readmitted in 1921.

departure also are compared. The curve of a declining mortality rate always flattens out rapidly and approaches a level which it is extremely hard to lower further.

It is not claimed that the statistics given herewith provide perfect comparisons but only that they eliminate some of the more flagrant and frequent errors. Table 1 is taken from the 1937 issue of the Epidemiological Report of the League of Nations, pages 67 and 68. Unless otherwise noted, it compares the infant mortality rate in various nations in 1920 with that in 1935.

The figures in table 2 are taken from Vital Statistics—Special Reports Vol. 5, No. 17, page 47, Bureau of the Census, March 1, 1938. The table includes states most nearly com-

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Society News.—The San Diego County Medical Society was addressed September 13 by Arthur I. Kendall, Ph.D., Chicago, on "Virus Diseases"; Dr. Philip E. C. Manson-Bahr, London School of Tropical Medicine, addressed the society August 17.

Institute on Health Education.—The Los Angeles Tuberculosis and Health Association recently sponsored an institute on community health education on the Los Angeles campus of the University of California. Ira V. Hiscock, C.P.H., professor of public health, Yale University School of Medicine, New Haven, Conn., conducted the program, which covered all phases of health education. The value of radio, motion pictures, newspapers, exhibits and group contacts was considered.

FLORIDA

Miami Visitors from Yellow Fever Foci Must Report to Health Authorities.—Since the flying time to Miami from actual or potential foci of yellow fever in South America has been shortened recently, the danger has increased of bringing passengers whose arrival, timed from the date of possible exposure, falls within the incubation period of the disease. To prevent introduction of the disease, Dr. George N. MacDonell, director of public health, issued an order July 1 requiring all such passengers who have within six days previous to their arrival been in any city, town or area which the U. S. Public Health Service has declared to be a focus, to report immediately to the health department. The visitors must remain under surveillance of the health department until six days from the time they departed from the danger zone in South America. If any febrile condition develops, the health department must be notified immediately. If the visitor should leave Miami before the six days has elapsed, he must report to the director of health and furnish information as to his movements. The order does not apply to travelers leaving the city immediately on arrival or to those who can show certificates of immunity to yellow fever.

GEORGIA

Society News.—A symposium on diseases of the biliary system was presented before the Fulton County Medical Society in Atlanta September 1 by Drs. Jean George Bachmann, Allen H. Bunce, James J. Clark and Daniel C. Elkin. Dr. Edward L. Graydon opened the meeting with "a few minutes of magic" and Dr. Frank K. Boland presided. Dr. Emmett D. Colvin presented a paper before the society in Atlanta September 15 entitled "Behavior of the Basal Metabolism in the Course of Developing Toxemia of Pregnancy: Correlation with Cholesterol, Placental Infarcts and Retinal Examination."

ILLINOIS

Meeting Dates Changed.—The Illinois State Medical Society has changed the date of its 1939 meeting from May 16-18 to May 2-4 to avoid conflict with the annual session of the American Medical Association in St. Louis May 15-19.

Society News.—At the second annual meeting of the Illinois Association for the Crippled in Chicago, September 15, Paul H. King, president, International Society for Crippled Children, spoke; John A. Lapp, LL.D., Chicago, discussed "The Value of a State Program for the Crippled," and Dr. Edward L. Compere, "The Program in Illinois." There was also a symposium on education, vocational training, guidance and employment. Dr. Compere was chosen president of the Illinois association at this meeting.—Drs. Clifford G. Grulee, Evanston, and William J. Dieckmann, Chicago, addressed the Knox and Warren county medical societies in Galesburg September 22 on "Care of the Premature Infant" and "Forceps Delivery" respectively.—The Adams County Medical Society was addressed September 12 by Dr. Ross A. Woolsey, St. Louis, on "Inguinal Hernia."—Dr. Ford K. Hick, Chicago, addressed the Peoria City Medical Society, September 20, on "Emotional Factors in Mental Hygiene."

Chicago

Personal.—Dr. Martha Wilson MacDonald, who has been in charge of the children's division of the department of psychiatry at Michael Reese Hospital for several years, has been appointed director of a new child guidance clinic in New Orleans. The new clinic has been made possible by a contribution from Mr. Samuel Zemurray, New Orleans, managing director of the United Fruit Company.—Mr. Paul Fesler, superintendent of Wesley Memorial Hospital since 1932, has resigned to become a consultant in hospital administration and construction.

Program on Sulfanilamide.—The Chicago Medical Society will hear a program on sulfanilamide at its meeting October 19. The speakers will be Paul Nicholas Leech, Ph.D., secretary of the Council on Pharmacy and Chemistry of the American Medical Association, on "Sulfanilamide, the Drug"; Dr. Eugene M. K. Geiling, "How Sulfanilamide Acts"; Dr. John S. Lockwood, Philadelphia, "The Clinical Status," and Dr. Paul R. Cannon, "Pathology." Mr. Walter G. Campbell, chief of the Food and Drug Administration, U. S. Department of Agriculture, Washington, D. C., will lead the discussion, and the following physicians will speak on the value of the drug: Drs. Joseph L. Baer, in obstetrics; Russell D. Herrold, urology; Julius H. Hess, pediatrics, and Italo F. Volini, internal medicine.

INDIANA

New Hospital for Tuberculosis.—Governor Townsend has appointed a committee to select a site for the construction of a tuberculosis hospital at some southern point in Indiana to cost \$650,000, 45 per cent of which will be financed by the PWA. Members of the commission include Arthur H. Sapp, Huntington, chairman; Thomas O'Mara, Terre Haute, vice chairman; Murray A. Auerbach, Indianapolis, secretary of the Indiana Tuberculosis Association, secretary; Lemuel A. Pittenger, president of the Ball State Teachers' College at Muncie, and Dr. Verne K. Harvey, Indianapolis, secretary of the state board of health.

Society News.—Dr. Ernest Perry McCullagh, Cleveland, addressed the Muncie Academy of Medicine September 13 on "Some Common Problems in Endocrine Therapy."—Dr. George S. Bond, Indianapolis, addressed the Carroll County Medical Society, Camden, September 8 on coronary artery disease.—Dr. Pierce MacKenzie, Evansville, addressed the Gibson County Medical Society, Princeton, September 12 on "The Three Stages of Labor, with Special Reference to Pain Relieving Preparations."—At a meeting of the Tippecanoe County Medical Society, Lafayette, September 13 Dr. Willis D. Gatch, Indianapolis, spoke on "Management of Wounds."—Dr. Carl J. Langenbahn, South Bend, addressed the Marshall County Medical Society, Plymouth, September 6 on "Chronic Gonorrhea in the Male."—Dr. Wayne R. Glock, Fort Wayne, addressed the Whitley County Medical Society, Columbia City, September 13 on "Backache."

LOUISIANA

Personal.—Dr. John Signorelli has been appointed medical director of the Orleans Parish School Board, succeeding the late Dr. Frederick L. Fenno.—Dr. Urban Maes, professor and head of the department of surgery, Louisiana State University Medical Center, New Orleans, received the honorary degree of doctor of science at the university's graduating exercises in Baton Rouge August 2.—Dr. William J. Rein, Pineville, has been appointed superintendent of the State Colony and Training School, Alexandria, it is reported. He will succeed Dr. Eugene M. Robards Jr., who resigned to devote his time to private practice.—Dr. Benjamin O. Morrison, Abbeville, has been appointed health officer of Acadia Parish.

MARYLAND

Semiannual Meeting of Medical Faculty.—The Medical and Chirurgical Faculty of the State of Maryland will hold its semiannual meeting at Chestertown October 12 with headquarters at the Armory. Dr. Frank B. Hines, Chestertown, president of the faculty, will give the address of welcome and Dr. Alexander Colclough Dick, the response. Dr. Alexander Randall, Philadelphia, will address the general meeting on "Diagnosis and Therapeutic Management of Early Obstructive Uropathies." A tea will follow the session.

MICHIGAN

Obstetrical Consultant Service.—Dr. Clair Folsome, instructor in obstetrics and gynecology, University of Michigan Medical School, Ann Arbor, has been appointed in charge of a newly created field consultant service in obstetrics recently inaugurated by the bureau of maternal and child health, state department of health. Dr. Folsome will cooperate with the maternal health committees of the county and district medical societies; his services are available to all physicians but at no time will he replace physicians who usually assist at deliveries, the state medical journal reports. The service may be obtained by any county medical society on request.

State Medical Election.—Dr. Burton R. Corbus, Grand Rapids, was chosen president-elect of the Michigan State Medical Society at its annual meeting in Detroit September 20 and Dr. Henry A. Luce, Detroit, was installed as president. Emeritus membership was conferred on Drs. John H. Jones, Dowagiac; George C. Hafford, Albion; Archibald B. Thompson, Grand Rapids; John W. Handy, Flint; Henry G. Berry, Mount Clemens; Ervin D. Brooks, Kalamazoo; Fred W. Freeman, Saginaw, and Joseph A. Crowell, Iron Mountain. The house of delegates of the society by unanimous vote approved the action of the House of Delegates of the American Medical Association at the recent special session in Chicago. The 1939 annual meeting will be held in Grand Rapids.

Certification in Graduate Education.—The Michigan State Medical Society held its first annual convocation for certification in graduate education in Detroit September 20 during its annual meeting. This convocation was the first of its type and was established to certify those physicians who attended special sessions in graduate education for four years. Physicians completing the first term, as it is designated, were made "associate fellows in graduate education." Fellowship will be conferred on completion of a second term. More than 500 physicians received certificates at the first convocation. Physicians unable to participate in the extramural courses covered in the program may take advantage of the intramural courses offered at the University of Michigan Medical School, Ann Arbor, and Wayne University College of Medicine, Detroit. Dr. Henry A. Luce, Detroit, presided at the convocation. Dr. James D. Bruce, in charge of graduate education at the state university, discussed "The Challenge of Medical Service" and Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, "Social Aspects of Medical Care." Drs. Henry Cook, Flint, and L. Fernald Foster, Bay City, presented the certificates.

MISSISSIPPI

Society News.—Dr. Julius L. Levy, Clarksdale, addressed the Coahoma County Medical Society and the Clarksdale Hospital medical staff August 10 on "Polydactylism."—Drs. Augustus Street and Willard H. Parsons, Vicksburg, addressed the Issaquena-Sharkey-Warren Counties Medical Society, Vicksburg, September 13, on "Surgical Diseases of the Gastrointestinal Tract."

MISSOURI

Society News.—Drs. Lawrence Schlenker and John M. McCaughan addressed the St. Louis Medical Society September 27 on "Prontosil in Pyopneumothorax" and "Posterior Gastrojejunostomy." Speakers at a meeting of the society September 20 were Dr. Carl F. Vohs on the special session of the House of Delegates of the American Medical Association and Rev. Alphonse M. Schwitalla, Ph.D., on the National Health Conference.

Dr. Goodwin Becomes Secretary-Editor Emeritus.—Dr. Edward J. Goodwin, for twenty-eight years secretary-editor of the Missouri State Medical Association, has retired with the title emeritus, and will be succeeded by Mr. Elmer Bartelsmeyer, who has been assistant secretary for several years. Dr. Goodwin graduated at the Washington University Medical Department, St. Louis, in 1894. He had been in private practice for a little longer than a year when an accident he suffered on alighting from a street car resulted in a paraplegia that totally incapacitated him for three years and made the future practice of medicine impossible. In 1902 he became associate recording secretary and official reporter of the state medical association; in 1903 assistant secretary; associate editor in 1905; editor in 1906 and in 1910 secretary-editor. He served as a member of the House of Delegates of the American Medical Association from 1909 to 1918 inclusive and from 1925 to 1934 inclusive. He was associate editor of the *Interstate Medical Journal* from 1903 to 1910, publishing the book "Medicine in Missouri" in 1905.

NEW JERSEY

Society News.—A symposium on diabetes mellitus will be presented before the section on medicine and pediatrics of the Academy of Medicine of Northern New Jersey, Newark, October 11, by Drs. Benjamin I. Saslow, Stuart Z. Hawkes and Anthony Russell Sherman.—Dr. Robert A. Kilduffe, Atlantic City, addressed a joint meeting of the New York and New Jersey chapters of the Association of Military Surgeons of the United States in Newark September 29 on "Disease and Destiny."—Dr. Harold D. Harvey, New York, addressed the Bergen County Medical Society, Englewood, September 20, on "Use and Abuse of Sulfanilamide."

NEW YORK

Hospital News.—Dr. Frederick C. Smith, formerly medical director of the U. S. Marine Hospital, Norfolk, Va., has been appointed acting director of Grasslands Hospital, Valhalla. He succeeds Dr. Arthur R. Bowles, who had been acting director since the resignation of Dr. Claude W. Munger in May 1937.

Society News.—Dr. Arthur J. Geiger, New Haven, Conn., addressed the Dutchess County Medical Society, Poughkeepsie, September 14, on "Practical Use of the Electrocardiogram in the Diagnosis and Follow-Up of Coronary Thrombosis."—The fall meeting and outing of the Associated Physicians of Long Island was held at Long Beach, L. I., September 29, with the following speakers, all of Hempstead: Drs. David Edward Overton, on "Longitudinal Sinus Thrombosis"; George B. Grauger, "Conduct of Labor"; Algernon S. Warinner, "Thyroid Disease from the Surgical Standpoint," and Louis H. Bauer, "Coronary Thrombosis."—Speakers at a meeting of the Medical Society of the County of Albany, Albany, September 28, were Drs. James S. Lyons on "Pyuria—Its Clinical Significance"; Arthur F. Holding, "Treatment of Malignant Disease of the Larynx," and Emanuel Martin Freund, "Observations and Analysis of Recent Hearing Surveys."—The New York State Association of Public Health Laboratories will hold its midyear meeting November 4 at the state laboratory in Albany.

New York City

Blood Tests for Marriage Licenses.—An increase of 4,000 blood tests given to persons seeking marriage licenses in August over the number given in July was reported by the New York City Department of Health. In July, the first month in which the law was operative, 6,656 premarital blood tests were given and in August 10,862.

Conviction for Making Noise.—An employee of the Interborough Rapid Transit Company power house at 110 East Nineteenth Street was convicted September 23 of violating the antinoise ordinance. Residents of the Gramercy Park section complained of the noise of the substation's dynamo. The court found that the noise constituted a violation of the ordinance because the doors of the power house were open while the dynamos were in operation. The judge suspended sentence.

Health Registration of School Children.—Twenty-five hundred mothers of school children joined the city school and health authorities when schools opened in September in the first health registration of the pupils. Members of the United Parents Association, the Queens Borough Federation of Mothers Clubs and other civic groups aided in the clerical work and interviewing in more than 600 schools. The registration cards identified each child by sex, race and date of birth; gave the name of the family physician and noted whether the child had had diphtheria, measles, whooping cough or scarlet fever. Space was left for other information to be obtained from a medical examination. Mothers were urged to take their children to a private physician if they could afford to do so; if they could not afford private care a request for health department examination and diphtheria immunization, if necessary, might be signed at the bottom of the card. Parents and guardians received a statement from Dr. John L. Rice, commissioner of health, explaining that a health certificate is required of each pupil on entering school, that vaccination is required by law and that diphtheria immunization is equally important. Parents able to afford an examination fee received a card to be filled in by a private physician and were told to return it within ten days. About 40,000 children were registered, a task beyond the capacity of the teachers, nurses or any available clerical staff, it was said.

NORTH CAROLINA

Society News.—Drs. Wilburt C. Davison, Durham, and Oren Moore, Charlotte, addressed the Catawba Valley Medical Society, Newton, September 13, on "Kidney Diseases of Children" and "Management of Obstetrical Malpresentations" respectively.—The Buncombe County Medical Society held a hobby show in Asheville August 31 with twenty-one exhibitors and 600 visitors.—E. N. Lawrence, D.D.S., Raleigh, addressed the Johnston County Medical Society, Princeton, September 20, on orthodontic problems.

Medical Symposium at Duke Centennial.—Duke University, Durham, begins a celebration of its centennial year with a "Symposium on Medical Problems" to be held October 13-15 in Page Auditorium in the school of medicine. William Preston Few, LL.D., president of the university, will give the welcoming address. Dr. Wilburt C. Davison, dean of the medical school, will preside. The speakers on scientific topics will be:

- Dr. Allen W. Freeman, Baltimore, Public Health Developments in the South.
- Dr. George W. McCoy, New Orleans, Leprosy in the United States.
- Dr. George Hoyt Whipple, Rochester, N. Y., Anemia and the Building of Hemoglobin in the Body.
- Dr. William H. Sebrell Jr., U. S. Public Health Service, Pellagra.
- Dr. Charles Franklin Craig, New Orleans, Amebiasis.
- Dr. Edward William Alton Ochsner, New Orleans, The Surgeon's Contribution to Treatment of Amebiasis.
- Dr. William G. MacCallum, Baltimore, Malaria.
- Dr. Arturo Lorenzo Carrion, San Juan, Puerto Rico, Rising Significance of Fungus Infections in Man.
- Dr. Albert M. Snell, Rochester, Minn., Tropical and Nontropical Sprue (Chronic Idiopathic Steatorrhea); Their Probable Interrelationship.

Thursday evening October 13 there will be a discussion of "The Future of American Medicine" by Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL; John P. Peters, New Haven, Conn., and Mr. Henry L. Mencken, Baltimore. Dr. Milton J. Rosenau, professor of epidemiology, University of North Carolina School of Medicine, Chapel Hill, will preside at this meeting. The scholastic year 1938-1939 has been designated as a time for celebration of a century of development which has resulted in the Duke University of today. The college was first named Union Institute, then was a normal college, and later Trinity College, which continues as the undergraduate school for men in the university. A formal celebration of the anniversary will be held April 21-23, 1939.

OREGON

State Program for Care of Low-Wage Earners.—The house of delegates of the Oregon State Medical Society at its annual meeting in August adopted a program for medical care of low income groups. The delegates first established a bureau of medical economics, whose services are to be made available to the component societies in developing special plans for care of low wage industrial groups. Each component society is to be asked to indicate whether the problem of this group and of contract practice is such that a special plan is desirable. Then on request of any component society, representatives of the bureau and legal counsel will be sent to make a survey of the local situation and advise in local plans. Any plans developed are to be submitted to the executive committee of the council of the state medical society for review as to conformity to policies and ethical standards. The statement of the delegates emphasized the principle that each local plan should limit its activities to the jurisdiction of the medical society by which it is approved except in special cases. Among other duties laid on the bureau of medical economics, it will develop uniform by-laws for plans, draft schedules of rates to subscribers, install uniform accounting practices as far as feasible, and develop general policies for guidance of local organizations. The delegates agreed to cooperate with the Oregon Association of Hospitals in the development of a plan for hospital care on a prepayment basis.

PENNSYLVANIA

Graduate Seminar at Wilkes-Barre.—The Wilkes-Barre General Hospital presented its Fourth Annual Postgraduate Seminar September 15. Guest speakers were Drs. Rupert F. Carter, New York, on "Surgical Management of Cholecystitis"; John A. Kolmer, Philadelphia, "The Toxicity and Therapeutic Applications of Sulfanilamide," and Irving S. Wright, New York, "Peripheral Vascular Disease."

Personal.—Dr. Martha Edith MacBride-Dexter, Harrisburg, secretary of health of the Commonwealth of Pennsylvania, recently received from the governor a meritorious service medal in recognition of her work during the flood of 1936.

—Dr. James Reid Martin, assistant professor of orthopedic surgery, Jefferson Medical College, Philadelphia, has been appointed chief surgeon at the Elizabethtown Hospital for Crippled Children.

Society News.—Dr. Roy R. Snowden, Pittsburgh, addressed the Cambria County Medical Society, Johnstown, September 8, on "The Anemias."—Dr. Philip F. Williams, Philadelphia, addressed the Northampton County Medical Society at the Country Club of Northampton County September 16 on "Maternal Welfare."—Dr. Eurifryn Jones, Camp Hill, addressed the Dauphin County Medical Society, Harrisburg, September 6, on "Differential Diagnosis of Hyperthyroidism."—At a meeting of the Lycoming County Medical Society, Williamsport, September 9, the speakers were Drs. Frederic C. Lecmner, Montoursville, on "Woldman Treatment of Peptic Ulcer"; Irvin T. Gilmore, Picture Rocks, "Chronic Ulcerative Colitis" and Chauncey L. Palmer, Pittsburgh, "Public Health Legislation."

Philadelphia

Bequests of Dr. de Schweinitz.—The University of Pennsylvania School of Medicine will eventually receive the bulk of the estate of the late Dr. George E. de Schweinitz to found a chair of ophthalmology. Except for one bequest of \$6,000, the estate of \$105,000 was left in trust for a sister of Dr. de Schweinitz. After her death \$5,000 will go to the College of Physicians of Philadelphia and the residue to the university. He also left his medical library to the College of Physicians. Dr. de Schweinitz died August 22.

Program of College of Physicians.—Drs. Homer F. Swift and Alfred E. Cohn, New York, will give the first lecture of the 1938-1939 season before the College of Physicians of Philadelphia October 12 on "Cardiac Diseases: Infectious and Noninfectious, Course and Consequences." Lectures for the coming months will be:

- Dr. Edward A. Strecker, Philadelphia, November 2, Should Psychoanalysis Be Purged?
- Dr. William K. Boyd, Toronto, December 7, Some Reasons for the Recent Increase in Bronchial Carcinoma.
- Dr. Walter Bauer, Boston, Jan. 4, 1939, Studies Pertaining to the Origin and Nature of Hypertrophic Arthritis.
- Dr. Cyril N. H. Long, New Haven, Conn., Feb. 1, 1939, Diabetes Mellitus in the Light of Our Present Knowledge of Metabolism.

TEXAS

Personal.—Dr. Bolivar J. Lloyd, medical director, U. S. Public Health Service, retired, Washington, D. C., has been appointed director of a recently organized health unit for Austin and Travis County. Dr. Benjamin M. Primer, recently health officer of Amarillo and Potter County, has been made assistant to Dr. Lloyd.—Dr. Robert L. Cherry, Kaufman, director of the district 3 health unit of the state department of health, has been appointed health officer of the Tyler-Smith County Health Unit to succeed Dr. Austin E. Hill, Tyler. Dr. Hill has been appointed director of communicable diseases, epidemiology and maternal and child health in the health department of Houston.

Society News.—Dr. Louis F. Knoepp, Beaumont, was chosen president of the Texas Tuberculosis Association at its recent meeting in El Paso. Dr. McIver Furman, Corpus Christi, is secretary.—Dr. Edward Stanley Pterman, Crowley, La., addressed the Jefferson County Medical Society, Beaumont, August 8, on "Goiter, with Special Emphasis on Hyperthyroidism."—Papers on nephritis were presented at a meeting of the Lubbock-Crosby Counties Medical Society, Lubbock, August 2, by Drs. Samuel C. Arnett Jr., Emerson M. Blake and Byron A. Jenkins, Lubbock.—Drs. Eutus P. Bunkley and Frederick E. Hudson, Stamford, addressed the Taylor-Jones Counties Medical Society, Abilene, July 12 on "Perforated Peptic Ulcer" and "Diseases of the Thyroid Gland and Other Disorders of Metabolism" respectively.

WASHINGTON

State Medical Election.—Dr. Warren B. Penney, Tacoma, was chosen president-elect of the Washington State Medical Association at the annual meeting at Bellingham August 31 and Dr. Harry E. Rhodhamel, Spokane, was installed as president. Dr. Vernon W. Spickard, Seattle, was reelected secretary. The next annual meeting will be held in Spokane.

King County Celebrates Golden Anniversary.—The King County Medical Society celebrated the fiftieth anniversary of its founding with a banquet at the Olympic Hotel, Seattle, September 24. Dr. Clarence W. Knudson, president of the society, gave a welcoming address and introduced the toastmaster.

Stored and Preserved Foods

The storage and preservation of foods, which is such a feature of modern civilization, has raised the question whether the treated foods are as nutritious as fresh foods. The Food Investigation Board has issued a report on the changes which all varieties of food undergo naturally and under the various methods of preservation. In addition to conducting investigations in England its experts visited laboratories abroad. The impression gained in the United States was that, while our country is in no way behind it in research on the handling and storage of foodstuffs, our application of science is not so forward. From time to time the members of the board have been asked whether food stored by modern methods, such as cold storage, gas storage and canning, is as nutritious as fresh foods. They referred the question to the Medical Research Council, which they thought more competent to deal with it, and on the authority of that body make the following statement:

"There is still so much to be learned about food and nutrition that it is impossible, in the present state of knowledge, to state categorically whether or not stored foods are as nutritious as fresh foods. Nor is it feasible to undertake research with a view to answering this question directly. Many years of intensive work on large groups of human beings would be entailed, and even then there would be little prospect of arriving at a definite decision, for further knowledge of the effect of dietary factors on nutritional processes would show that the results achieved would have to be reconsidered. Nevertheless, useful information can be obtained by comparing the chemical composition of stored foods with that of fresh foods, and the general conclusion can be accepted that relatively little less of known constituents is present in foods stored by modern methods. Moreover, in animals satisfactory nutrition has been maintained with diets composed solely of stored foods. The available evidence therefore suggests that modern methods of storing foods cause little depreciation in their nutritive value; in fact, it may be said that food of good initial quality that has been stored by the best modern methods is likely to be superior in many respects to similar food that, though still technically fresh, is in reality stale. One substance of important biologic significance, associated especially with fresh fruit and vegetables, namely vitamin C or ascorbic acid, is easily destroyed by heat, applied either in ordinary cooking or in canning; to a less extent vitamin B₁ is liable to be similarly affected."

THE STORAGE OF FISH

During the last ten years there has been an increase in the care with which fish is handled and stored on ice in trawlers. Storage in ice will keep fish fresh for from ten to twelve days. Beyond this period fish cannot be kept fresh, because bacteria can multiply at the temperature of melting ice, and some more powerful method is required. At the Tory Research Station the method has been worked out of freezing fish in brine at a temperature of -20°C . and storing them at the same temperature or, better, at a temperature of -30°C . White fish so treated retain their original freshness for at least six months. Indeed lemon soles have been kept at the station in a palatable condition for as long as two years. Thus a highly perishable article has been converted into one relatively imperishable. The industry is now considering the commercial possibilities of this method. The report recommends the freezing of that part of the trawler's catch which cannot be landed within twelve days. The fish should be absolutely fresh when frozen.

Test for Hydrogen Cyanide in Industry

The Department of Scientific and Industrial Research has issued a pamphlet describing a standard method for detecting hydrogen cyanide in industry. This gas is encountered in concentrations which may be dangerous in blast furnaces, dyestuff works, gas works and coke ovens, gilding works and gold mines. It is used in the fumigation of ships and buildings. In addition to the usual danger of inhalation there is danger to a person wearing an efficient respirator—absorption through the skin, which is greater if the skin is wet with sweat. The ordinary tests for hydrocyanic acid are not sufficiently sensitive to detect the low concentrations likely to be encountered in the atmosphere. Moreover, they are interfered with by the presence of other gases. The standard method of the department consists in drawing samples of the atmosphere to be tested through a piece of test paper impregnated with benzidine and copper acetate or with congo red and silver nitrate. The test papers are prepared from extra thick white filter paper; they are immersed in the solution, dried and then used immediately. The colors produced are compared with standards of varying depth which are supplied with the pamphlet. These, in conjunction with the number of strokes given to the pump, show the concentrations of hydrogen cyanide down to 1 in 100,000. One part in 50,000 will produce slight symptoms after several hours, and one part in 10,000 is dangerous after an hour.

Welfare in Factories

July 1 there came into operation a new factories act, which affects in a variety of ways the working conditions of nearly 6,000,000 persons. The object is to secure safe and healthy conditions of employment in some 250,000 factories (a term which now includes workshops). The immensity of the undertaking is shown by regulations covering such diverse fields as sanitary accommodation, conditions under which certain operations may be carried out at unfenced machinery, the provision of goggles or screens for protecting the eyes, the employment of young persons on night shifts, the calculation of overtime and the arrangement of intervals for meals and rest for women and young persons to meet seasonal or special pressure of work. Employers are required to post in their factories notices in a prescribed form specifying the scheme of working hours for women and young persons within the maximum limit and the intervals fixed for meals and rest. In general the permitted hours of employment for these workers will be reduced to forty-eight a week. Anything in excess will be overtime and will be strictly limited. Those under 16 will not be allowed to work overtime, and their working time has been reduced to forty-four hours a week. Women and young persons will not be allowed to begin work earlier than 7 a. m. or to end it later than 8 p. m., and they must all finish by 1 p. m. on Saturday. Those under 16 must end their work on other days by 6 p. m. Factory inspection has been intensified and the staff of inspectors increased.

Gastric Complaints of London Busmen

In a recent strike of London busmen the argument was used that their working conditions were so detrimental as to render them specially affected with gastric complaints. An investigation was therefore made by Dr. Bradford Hill (medical statistician) on behalf of the Industrial Research Board. He has made a report which shows that in 1933-1935 the omnibus drivers had a relative excess of gastric sickness (in proportion to all sicknesses) of from 12 to 14 per cent over the figure for tram-car drivers, while omnibus conductors had an excess of from 15 to 18 per cent over tramcar conductors. Expressed in another way, one day in six and one-half total days of sickness recorded by the two groups of omnibus workers was attributed to gastric causes, compared with one day in seven and one half for tram-car workers. The report affirms that it is impossible to determine from the existing mortality statistics that the average life

of an omnibus worker is lower than that of other occupational groups. Indeed, figures show that drivers of motor vehicles and steam wagons have a better mortality than that of all occupied civilian males in England and Wales of the same ages. Since the omnibus strike a new agreement has been reached providing for improved terminal facilities and breaks in each spell of duty equivalent to not less than 5 per cent of the journey's time. An investigation is proceeding with a view to discovering the causes of the gastric sickness and measuring the influence, if any, on the omnibus workers of irregular meals, nervous strain, exhaust fumes and speedier service.

PARIS

(From Our Regular Correspondent)

Sept. 10, 1938.

Symposium on Cancer of the Breast

At the June 20 meeting of the French Association for the Study of Cancer a series of papers was read on the evaluation of transillumination as a diagnostic method and on the end results of operative treatment of cancer of the breast.

The first paper was by Dr. René Huguenin of the Paris Cancer Institute, who has used the transillumination method in 800 cases in six years. He said that it is necessary to change the older notions with regard to differentiating benign from malignant lesions in the female breast by inspection and palpation. In a large number of cases of early involvement in which the diagnosis of a malignant process was confirmed by biopsy, palpation showed that the tumor was nodular and sharply circumscribed by a perineoplastic reaction of the surrounding stroma. This physical characteristic has hitherto always been considered typical of a benign condition. In former times it was taught that a malignant lesion in its early stages was not adherent to the overlying skin, so that dimpling did not follow when the skin was grasped between the thumb and index finger. This negative result of palpation meant that the tumor was located deeply in the gland and separated from the skin by the premammary fat. It is evident at present that even the most painstaking examination will not be able to determine definitely whether a deeply seated neoplasm is a simple cyst or a neoplastic nodule, because of the manner in which the overlying fat masks such a lesion. It was also formerly taught that a diffuse but extensive induration occupying a quadrant or more of the breast was malignant. Many such growths have been needlessly operated on. At the Paris Cancer Institute a number of cases have been observed of such massive indurations due to benign canalicular and acinous hyperplasia. It would seem paradoxical, but recent observations show that extensive and noncircumscribed indurations are frequently benign, whereas small, sharply demarcated nodules are frequently malignant. Even with regard to enlargement of the axillary lymph nodes, our former notions must be revised. Recurrent attacks of hyperplastic mastitis can be accompanied by indurated, painless, axillary lymph nodes, while in some cases of early cancer no involvement of lymph nodes is apparent even on histologic examination. In many cases of cancer the enlarged lymph nodes show no evidence of malignancy. It may even happen that they are tuberculous, as was found by Huguenin and Redon in several cases. The clinician should be warned against giving androgenic or estrogenic substances when a diagnosis of a single or multiple cyst has been made, because there is a possibility of the coexistence of a cancer in the wall of such a cyst or even in simple massive hyperplasia.

After trying all other recently advocated methods, such as plain roentgen examination and injection of opaque media, Huguenin now employs only transillumination, the technic of which can easily be learned by the surgeon. The results of this newer method of diagnosis are not infallible. At the Paris Cancer Institute they were verified by histologic exami-

nation in only 80 per cent of the cases. Perhaps the percentage of erroneous diagnoses can be reduced as experience increases and the technic of the source of illumination is perfected. Some of the processes which were regarded as malignant after transillumination proved to be tuberculous mastitis or hemorrhagic cyst, potentially malignant conditions, so that operative intervention was not in vain. The chief value of transillumination is that it serves as a guide for treatment. If there is no evidence of opacity, the patient should not be operated on but should be followed and reexamined from time to time. If, however, transillumination reveals a more or less extensive opacity, so that a diagnosis of cancer appears probable, a biopsy should be done if possible before operation. If a diagnosis of cancer has been made by palpation and transillumination gives a negative result, biopsy should nevertheless be done as soon as possible. Transillumination is of value in indicating the seat of a lesion, so that radical operations can at times be avoided. Often transillumination is negative and the clinical examination positive. In such cases, only biopsy can decide which diagnosis is correct. The objection may be raised against transillumination that, after all, a preoperative biopsy must be done if the results of the clinical and the transillumination examination differ. The chief advantage of transillumination is that it serves as a guide to the location of a lesion which should be subjected to biopsy, thus avoiding the removal of a cyst or hyperplastic nodule and leaving a small cancer which is visible by transillumination.

MICROSCOPIC EXAMINATION DURING OPERATION

A second paper, on better end results as the result of microscopic examination during operation, was read by Dr. Georges Lardennois of Paris. The prognosis of cancer of the breast before involvement of the axillary lymph nodes has taken place is as favorable as that of the majority of other cancers. Since 1923 Dr. Lardennois has insisted on a microscopic examination being made during all operations on the breast. Up to 1934 Professor Leroux examined 118 cancers by means of the freezing technic; only once was an erroneous diagnosis made, and this was corrected as soon as more material for study was available. Since 1934 a special technic termed *ultrapaque* has been used by Professor Leroux, and every one of his decisions as to whether specimens examined during operation indicated a benign or malignant condition has been confirmed by later (postoperative) microscopic examination. Up to Feb. 1, 1934, a benign condition was found in fifty-four and a malignant process in sixty-four cases. Since 1934, as a result of earlier exploration and immediate microscopic examination during operation, the percentage of lesions found to be benign has increased. In seventeen of the 118 cases in which operation was performed before 1934, i. e. four and one-half years before the follow-up statistics were collected, the diagnosis was doubtful at the time of operation and it has been impossible to determine the end results. In six others an erroneous diagnosis had been made. The general practitioner's attention ought to be called to the necessity of not waiting to make a diagnosis until retraction of the nipple, wrinkling of the skin overlying the suspected neoplasm and palpable axillary lymph nodes are found. When these exist, it is too late to expect a favorable end result, because internal metastases have already taken place. With the most malignant conditions all these signs may be lacking. When serous or hemorrhagic exudation from the nipple is seen, no one is able to say whether the intracanalicular neoplasm is benign or malignant. In four of seven such cases the process was found to be benign, and in three it was malignant. The clinical diagnosis of a tumor of the breast is presumptive and becomes positive only after microscopic examination.

Dr. Lardennois criticized the method so often employed of making a biopsy several days before operation, because the traumatism, formation of hematoma and local congestion appear

to favor visceral metastasis. Before he adopted the method of always examining the specimens removed at the beginning of an exploratory operation, he observed some very unfavorable end results when an interval of several days was allowed to elapse between the biopsy and the operation itself. Of sixty-four patients (eight of whose neoplasm was intracanalicular) operated on prior to 1934, twenty-six, including three males, were living from four and one-half to fifteen years after operation. Such favorable end results would be even better if every general practitioner insisted on immediate exploration and removal of every suspected tumor of the breast. The incision for exploration employed by Dr. Lardenois is a submammary one, and the suspected area is removed with the electric bistoury. While the vessels are being ligated, the microscopic examination can be made and the decision reached as to whether a radical operation should be done.

END RESULTS

The third paper was read by Professor Ducuing of Toulouse and cited the end results in 243 cases of cancer of the breast in which operation had been done in his clinic. The diagnosis of a malignant process was confirmed by microscopic examination in every case. In every such survey of end results it is essential to exclude cases in which only palliative operations were done as compared to those in which the operation was radical. There were forty-six cases in which simple palliative procedures were employed to remove extensive areas of ulceration and control bleeding and no attempt was made to extend the operation to the axillary lymph nodes. Of the forty-six apparently hopelessly ill patients, 30 per cent lived more than three years and 13 per cent more than five years. When a radical operation was performed, it was found that 40 per cent of the patients presented no evidence of recurrence within three years and 31 per cent from five to nine years after operation. This more than five year survival percentage is perhaps lower than that of some other clinics but appears satisfactory when one takes into consideration the fact that the wider indications for radical operation made it possible to include many patients who might have been refused such a procedure by other surgeons. This survival rate is also perhaps lower than that for irradiation alone, but not all the patients treated by this method had a microscopic examination as a control. In the future, perhaps a higher rate of five year survivals may be attained by combining radical procedures with postoperative irradiation.

The end results of the operative treatment of cancer of the breast at the Curie Foundation and at the Hôtel-Dieu were presented by Dr. André Tailhefer of Paris. During the past eleven years, 160 cancers of the breast have been operated on. The end results in forty-six patients who have not shown any signs of recurrence from five to eleven years after operation were the only ones submitted. An incision which permitted removal of a large cutaneous area was used in all cases. In eleven of the forty-six cases microscopic examination of the axillary lymph nodes failed to reveal any evidence of cancerous involvement. Ten of the eleven patients are apparently well from five to nine years after operation. Only one patient died of sternal metastases; his death occurred a year after operation. Of thirty-two patients whose axillary lymph nodes were already involved by extension from the breast cancer, fourteen are apparently cured. The interval since operation varies from eleven years and two months to eleven years and four months. A study as to the incidence of metastases in the remaining eighteen cases shows that the supraclavicular and intrathoracic lesions are the most common and that the incidence is relatively high when the cancer is located in the inner half or in the deeper portions of the breast. Forty-two of the 160 patients operated on during the past eleven years showed absence of any involvement of the axillary lymph nodes. There are two forms of supraclavicular metastases; in one the lymph nodes are deeply located and inaccessible, whereas for the other,

situated well above the clavicle, removal is still possible. During recent years, microscopic examination of tissue removed during the operation, as recommended by Lardenois, has been employed in the majority of cases. The conclusions reached by Dr. Tailhefer were that radical operation will be followed by cure in a relatively high percentage of cases provided that only favorable cases are selected for operation; hence he carried out the radical procedure only in cases in which the tumor did not exceed from 4 to 5 cm. in diameter and there was slight or no involvement of the axillary lymph nodes. If microscopic examination confirms the absence of such an extension, nothing further is done. If, however, the axillary nodes are shown to be invaded, postoperative roentgen or radium treatment is directed toward the supraclavicular and internal mammary chains of lymph nodes. To patients presenting a tumor more than 4 or 5 cm. in diameter or accompanied by evident involvement of the axillary nodes, seen on gross or microscopic examination, preoperative roentgen irradiation is given for a month before the radical operation.

DIFFICULTIES OF DIAGNOSIS

The next paper was by Prof. Henri Hartmann and called attention to the difficulty of making a diagnosis in cases of mammary tuberculosis of the pseudoneoplastic type, in certain cases of localized nontuberculous chronic mastitis and in cases of chronic abscess of the breast. He was opposed to preoperative biopsy or removal during operation of tissue for microscopic examination, even with the more rapid methods now employed, because of the danger of the migration of cancer cells into lymph spaces which had been opened during the preliminary exploratory procedure. Another objection is that if the pathologist gives a negative opinion of the specimen examined at operation, the tissue submitted to him may not include the cancer area. Professor Hartmann prefers to remove a large segment of the breast at the first operation, i. e. to do a partial resection then and a more radical one later. Some patients may object to two operations, but his end results in thirteen cases, with two eight year survivals and one ten year survival, show that the two step procedure has many advantages. Recurrence has been observed as late as ten years or more after a radical operation. Although local recurrence may not be evident, many patients die of visceral metastases. Irradiation alone is to be recommended in cases of diffuse carcinomatous mastitis and in cancers with extensive ulcerations.

INVOLVEMENT OF AXILLARY NODES

The last paper in the symposium was read by Dr. Desmarest, who agreed with previous speakers as to the part played by involvement of the axillary lymph nodes in the prognosis of cancer of the breast. Of 100 patients on whom the radical operation had been performed by him, fifty-four died within the first three years, fourteen during the next two years, one during the sixth year and three during the seventh year. It is misleading to state that a patient has survived a certain number of years after operation. It would be more correct to state when the first signs of a recurrence had appeared, because in a number of cases life becomes insupportable two or three years before death. Dr. Desmarest's results were so poor because the axillary nodes were involved at an early period in the evolution of the cancer in a large percentage of his cases. He expressed the opinion that when there is evidence of advanced involvement of these nodes, a radical operation is not only of no avail but may do more harm than good. The results of palliative treatment of inoperable cancers, as Professor Ducuing had shown earlier in the symposium, were almost as good as those after attempts to do a radical operation. Dr. Desmarest said that if there is no involvement of the axillary nodes, removal of the breast alone is indicated. If the nodes are already involved, there is a risk of dissemination of the cancer to the supraclavicular lymph nodes or even to the viscera during a radical operation.

Aug. 29, 1938.

The Decrease in Medical Students

The number of candidates for medical schools this year suddenly decreased. There were only 1,241 candidates for thirteen medical colleges. Of these colleges, eight had far fewer candidates than they had expected. This may have been due in part to the fact that all the colleges give their examinations on the same day, but the deepest cause must be the unpopularity of medical practice at present. Medicine in this country has long been the most favored profession, at which practitioners succeeded in accumulating wealth. Many bright students applied to the medical colleges. Great physicians did much to raise the level of medicine in this country to that in other countries in a short period. People in general began recently to have a different idea of medicine. They now insist that it ought not to be a free profession and that medical practice should be strictly controlled by the government. This tendency is a menace to physicians. With the development of national health insurance, the income of physicians decreased, and people gradually began to prefer a hospital physician to an independent practitioner. There are, the health office reports, 57,581 physicians, of whom 51,597 are practitioners. Less than half of the practitioners are independent, and the rest are employed in hospitals on a salary basis. As future physicians will be merely salaried men, graduates of high schools prefer other more promising professions. A conference of the presidents of all government universities was held to talk over this matter, and they agreed to propose to the education office measures to meet the situation.

The Board for Disabled Soldiers

The board for disabled soldiers was recently created as a branch of the welfare office, and 35,300,000 yen was appropriated by the Diet for this fiscal year. General Honjyo was appointed president. The chief aim of this institute is to give disabled soldiers and their families ample relief, medical and otherwise. This year there are to be established twenty-five new sanitariums, each able to accommodate 500 persons with tuberculosis, at a cost of 24,610,000 yen. * A home for soldiers suffering from mental disease will be established as the next work. Ten sanatoriums will be established at hot springs near the division headquarters, where disabled soldiers will be cared for and treated, each for about two months. This year about 3,000 men will be admitted. Until the completion of all the establishments, the private institutes throughout the country will be entrusted with the treatment of soldiers. A home for crippled soldiers in Tokyo is to be established by a few business men at their own expense, independently of the government institute. Two million yen will be contributed for the fund, and the building is expected to be completed by the end of this year.

Venereal Disease Among Returned Soldiers

The present Sino-Japanese trouble is thought to have caused an outbreak of venereal diseases when so many soldiers returned from the front after a long absence from home. A sum of 1,343,654 yen was given by the government to be used in preventing these diseases. As the first measure, ninety-four venereal disease clinics are to be built in the larger cities. Returned soldiers will be examined at these clinics before discharge, and those infected will not be discharged until they have completely recovered.

Physical Condition of Shop Workers

The results of the physical examination of conscripts this year revealed as usual many defects in their physical condition. The conscripts fall into two groups: (1) those who left primary school at the age of 12 and (2) those who left at the age of 14. The conscription examinations show that there is little difference between the two groups in the rural areas,

where the conscripts do not become shop workers, but a great deal in the cities and manufacturing centers. In cities, workers less than 12 years of age work under very unhealthy conditions, while in the farming villages they work under favorable conditions. The following statistics pertain to the conscription examinations of the young shop workers in the larger cities. Of 997 boys who had left the eight year primary school and were engaging in business, 317 were passable and 323 were second grade passable (64 per cent), while 357 were not able to pass (35.7 per cent). Of the same number of those who left the six year school, 286 were passable and 282 were second grade passable (56.7 per cent), while 429 did not pass. Physical development in this country is complete for the female at the age of 19 and for the male at the age of 20. The present habit of employing young boys and girls in shops or offices is far from ideal, for they are often obliged to work from morning till night without any time for rest. Some of them are forced to go in the evening to the young men's schools, which close at 9 o'clock. It is reported that the welfare department has drafted a law for protecting young shop workers.

Research Institution on Mount Fuji

The building of the Japanese institute for research in military aviation medicine, under construction since last summer on the top of Mount Fuji (3,778 meters), was completed in July. The opening ceremony was held in August, with many prominent military surgeons present. The costly building contains fourteen rooms with complete protection against cold, and it is situated next door to the station belonging to the Central Meteorologic Observatory. There will be a standing staff consisting of two army surgeons, and two men from the military medical school will alternate yearly as assistants. The chief research will be on such subjects as the physiologic state of the human body at a high altitude and the hygiene of aerial navigation. This is the first institution of this kind in the country.

Waichiro Okada Is Dead

Dr. Waichiro Okada, honorary professor of the Tokyo Imperial University and president of the Showa Medical College, died of asthma June 30 at the age of 75. He was born in a little town on Shikoku Island, in middle Japan. He graduated with honors from the medical college of the Tokyo Imperial University in 1889; in 1895 he was appointed assistant professor in the department of surgery, and the next year he was sent to Germany to study otorhinolaryngology, staying there about five years. On his return to the Tokyo Imperial University from abroad in 1900, he opened the first independent department of otorhinolaryngology at a university in this country. The next year he was appointed professor. He retired from the university in 1924. During his twenty-five years there he did much for the development of otorhinolaryngology. After retiring he founded the Showa Medical College in Tokyo. He was for forty years the president of the Japan Society of Otorhinolaryngology. He was also a politician. He offered his services to the municipal administration of the city of Tokyo and was an assemblyman for many years.

Marriages

RICHARD HARDY APPLE, Culver, Ind., to Miss Ella Frances Parker of Salisbury, N. C., in Albemarle, N. C., September 3.
PROSSER HARRISON PICOT, Richmond, Va., to Miss Elmyra Davidson Williams of Wytheville, September 3.
GERHARD K. MANSKE, Texas City, Texas, to Miss Hallie Andrews of Wichita Falls, in Austin, June 25.
GILLIAM SWINK HICKS, New York, to Miss Cornelia Griffin Williams of Memphis, Tenn., July 2.
JACOB H. KRESS, Thomasville, N. C., to Dr. ESTA JOYCE LEVY of Suffolk, Va., August 11.

Deaths

Charles Phillips Emerson • Indianapolis; Johns Hopkins University School of Medicine, Baltimore, 1899; professor of medicine and dean, Indiana University School of Medicine, 1911-1932, and research professor since 1932; formerly associate in medicine at his alma mater; assistant professor of medicine at Cornell University, 1909-1910; member of the Association of American Physicians; past president of the Association of American Medical Colleges and the National Committee for Mental Hygiene; superintendent of the Clifton Springs (N. Y.) Sanitarium, 1908-1911; during 1931 and 1932 was a member of a commission, sponsored by the Laymen's Foreign Mission Inquiry, to study educational and medical missions in the Orient; in 1934 was awarded the honorary degree of doctor of science by Amherst College, Amherst, Mass., his alma mater; author of "Pneumothorax," "Clinical Diagnosis," "Hospitals for Children" and "Essentials of Medicine" and joint author of "Emerson and Betts Physiology and Hygiene," "Physical Diagnosis," "The Nervous Patient" and "Text Book of Medicine"; aged 66; died, September 26, of bronchopneumonia.

Thomas Richmond Boggs • Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1901; at various times associate professor of medicine, associate professor of clinical medicine, instructor and associate in medicine at his alma mater; member and past president of the Association of American Physicians; member of the American Society for Clinical Investigation; was decorated for services during the World War and later was a colonel in the medical reserve corps; on the staffs of the Johns Hopkins Hospital, Baltimore City Hospital, Church Home and Infirmary, Union Memorial Hospital and the Hospital for Women; consultant to the Veterans Bureau at Washington; aged 62; died, September 2, at Fredericksburg, Va.

Leroy Watkins Hubbard • Mount Vernon, N. Y.; University of the City of New York Medical Department, 1883; director of the extension work for the Warm Springs Foundation in Georgia, where he was formerly surgeon in chief; connected with the city health department from 1897 to 1914; member of the American Academy of Orthopedic Surgeons; in 1934 was awarded the golden key of merit by the American Congress of Physical Therapy; aged 81; died, August 31, in a sanitarium at Clifton Springs, N. Y., of arteriosclerotic heart disease and coronary occlusion.

Thomas Archibald Davis • St. Petersburg, Fla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1885; member of the Illinois State Medical Society; fellow of the American College of Surgeons; formerly professor of surgery and clinical surgery at his alma mater; at one time president and professor of surgery at the Illinois Post-Graduate Medical School; for many years surgeon to the Cook County Hospital and the West Side Hospital, Chicago; aged 80; died, September 19, at his summer home in Delavan, Wis.

Henry Howard Whitehouse • New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; at one time professor of dermatology at the New York Post-Graduate Medical School, Columbia University; instructor of dermatology and syphilology at Cornell University Medical College, 1902-1907; member of the American Dermatological Association; served in various capacities on the staff of the New York Skin and Cancer Hospital; aged 74; died, August 24, in Mystic, Conn.

Frederick Henry Flaherty • Syracuse, N. Y.; Syracuse University College of Medicine, 1896; member of the House of Delegates of the American Medical Association, 1927-1932, 1935-1937; past president of the Medical Society of the State of New York and of the Onondaga County Medical Society; professor emeritus of clinical surgery at his alma mater; fellow of the American College of Surgeons; aged 64; surgeon to the Syracuse Memorial Hospital and St. Joseph's Hospital, where he died, September 7, of cerebral hemorrhage.

Raphael Burke Durfee • Bisbee, Ariz.; Georgetown University School of Medicine, Washington, D. C., 1900; past president of the Arizona Public Health Association; at one time professor of anatomy at the College of Physicians and Surgeons, Los Angeles; city bacteriologist for Los Angeles, 1908-1916; city and county health officer; Veteran of the Spanish-American and World wars; aged 62; died, July 24, of coronary thrombosis.

Maurice Farvish Lautman • Hot Springs National Park, Ark.; Yale University School of Medicine, New Haven, Conn., 1911; consultant to the U. S. Public Health Service Clinic;

served during the World War; on the staff of the Levi Memorial Hospital; author of "Arthritis and Rheumatic Disease"; aged 48; died, September 24, of coronary thrombosis.

Charles William Stevenson • Wichita Falls, Texas; University of Texas School of Medicine, Galveston, 1912; fellow of the American College of Physicians; served during the World War; medical director and owner of Dr. White's Sanitarium and on the staff of the Wichita General Hospital; aged 49; died, July 31, of pneumonia.

William Matthew Dugan • Battle Creek, Mich.; University of Michigan Medical School, Ann Arbor, 1916; fellow of the American College of Surgeons; past president of the Calhoun County Medical Society; on the staff of the Leila Y. Post Montgomery Hospital; aged 53; died, August 22, of abdominal carcinoma.

William J. Trefethen, Wilton, Maine; College of Physicians and Surgeons, Baltimore, 1894; member of the Maine Medical Association; formerly member of the state legislature and senator; aged 71; on the staff of the Franklin County Memorial Hospital, Farmington, where he died, July 24, of cerebral hemorrhage.

Bertell Laroy Talbot, Milford, N. H.; Harvard University Medical School, Boston, 1896; member of the Massachusetts Medical Society; at one time member of the board of health of Peterboro; served during the World War; formerly a member of the Veterans Bureau; aged 66; died, July 14, of heart disease.

John Aloysius Farrell • West Chester, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; past president of the Chester County Medical Society; served during the World War; on the staff of the Chester County Hospital; aged 63; died, July 30, of coronary thrombosis.

Claude Dickson Scaff, Clarksville, Texas; Kentucky School of Medicine, Louisville, 1905; member of the State Medical Association of Texas; past president and secretary of the Red River County Medical Society; county health officer; aged 59; died, July 26, of rheumatic heart disease.

Reeves Bailey Van Duzer • East Orange, N. J.; Columbia University College of Physicians and Surgeons, New York, 1930; on the staff of the Montclair (N. J.) Community Hospital; aged 34; died, July 7, in the Orange (N. J.) Memorial Hospital of acute nephritis and uremia.

John Blois Watson • Raleigh, N. C.; University of North Carolina School of Medicine, Raleigh, 1908; formerly professor of materia medica, pharmacology and therapeutics at the Leonard Medical School; aged 53; died, July 15, in the Rex Hospital of septic endocarditis.

Francis Michael C. Rochford, Brooklyn; Long Island College Hospital, Brooklyn, 1903; member of the Medical Society of the State of New York; served during the World War; director of the department of pediatrics, Misericordia Hospital; aged 60; died, July 31.

Samuel Alaga Roe, Corvallis, Ore.; Missouri Medical College, St. Louis, 1897; New York Homeopathic Medical College and Hospital, 1898; member of the Pacific Coast Oto-Ophthalmological Society; formerly on the staff of the Corvallis General Hospital; aged 61; died, July 14.

John Davis Colson, Pageland, S. C.; Medical College of the State of South Carolina, Charleston, 1909; served during the World War; at various times member of the town council and county board of education; aged 49; died, July 18, in the McLeod Infirmary, Florence, of nephritis.

Robinette Burns Hayes, Hillsboro, N. C.; University of Maryland School of Medicine, Baltimore, 1906; member of the Medical Society of the State of North Carolina; served during the World War; aged 61; died, July 16, in the Watts Hospital, Durham, of cholelithiasis.

William Alex Gordon, Hagerstown, Md.; College of Physicians and Surgeons, Baltimore, 1893; member of the Medical and Chirurgical Faculty of Maryland; past president and secretary of the Washington County Medical Society; aged 71; died in July of endocarditis.

Harold James Durant • Paterson, N. J.; Tufts College Medical School, Boston, 1927; fellow of the American College of Surgeons; served during the World War; aged 41; on the staff of St. Joseph's Hospital, where he died, July 15, of typhoid and pulmonary embolism.

Luke Robinson, Covington, Ga.; Southern Medical College, Atlanta, 1893; member of the state board of medical examiners; member of the city council and board of education; aged 69; died, July 23, in the Emory (Ga.) University Hospital of cirrhosis of the liver.

Arthur Thurston Newcomb * Pasadena, Calif.; Baltimore Medical College, 1893; served during the World War; member of the American College of Physicians; on the staff of the Huntington Memorial Hospital; aged 65; died, July 18, of cerebral embolism.

Roy Raymond Bair, Newark, N. J.; Chicago College of Medicine and Surgery, 1916; New York Homeopathic Medical College and Flower Hospital, New York, 1918; aged 57; died, July 23, in the Presbyterian Hospital of septicemia following a prostatectomy.

Joseph C. E. Fritch, Cleveland; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1896; aged 71; on the staff of the Lutheran Hospital, where he died, July 25, of myocarditis and gangrenous appendicitis.

Henry Gatrell, Fairfield, Fla.; Medical Department of Tulane University of Louisiana, New Orleans, 1898; member of the Florida Medical Association; aged 64; died, July 24, in a hospital at Orlando of cirrhosis of the liver and arteriosclerosis.

Paul Renger * Hallettsville, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1901; owner of the Renger Hospital; aged 61; died, July 26, in the Nix Hospital, San Antonio, of nephritis, myocarditis and bronchiectasis.

Mark William Baxter, Salt Lake City; Drake University Medical Department, Des Moines, Iowa, 1892; member of the Utah State Medical Association; medical director of the Mountain View Sanatorium; aged 88; died, July 22, of arteriosclerosis.

Bernard Leo O'Donnell, New York; New York University Medical College, 1898; member of the Medical Society of the State of New York; aged 65; died, July 18, in St. Francis Hospital, of perirectal abscess and cardiorenal arteriosclerosis.

Richard Ellwood Peteferd, Springfield, Ohio; Ohio Medical University, Columbus, 1906; member of the Ohio State Medical Association; aged 55; died, July 29, in the City Hospital of carbuncle with multiple abscesses of kidneys and lungs.

Fred Allison Bower, Uhrichsville, Ohio; Ohio State University College of Medicine, Columbus, 1925; member of the Ohio State Medical Association; aged 38; died, July 25, in the Twin City Hospital, Dennison, of malignant hypertension.

Walter Hugo Rosenfield, Louisville, Ky.; University of Louisville Medical Department, 1907; member of the Kentucky State Medical Association; served during the World War; aged 59; died, July 5, in SS. Mary and Elizabeth Hospital.

John Silverwood Sutcliffe, El Dorado, Kan.; Missouri Medical College, St. Louis, 1898; Marion-Sims College of Medicine, St. Louis, 1899; aged 77; died, July 19, in the Susan B. Allen Memorial Hospital of cerebral hemorrhage.

Henry Harris * San Francisco; Johns Hopkins University School of Medicine, Baltimore, 1899; formerly associate clinical professor of medicine, University of California Medical School; aged 63; died, July 7, of coronary disease.

Edward Carroll Brannon, Waco, Texas; Baylor University College of Medicine, Dallas, 1913; member of the State Medical Association of Texas; aged 48; died, July 23, in a hospital at Fort Lyon, Colo., of perforated gastric ulcer.

Reuben Hill Born, Montoursville, Pa.; Bellevue Hospital Medical College, New York, 1887; member of the Medical Society of the State of Pennsylvania; aged 73; died, July 14, of arthritis, arteriosclerosis and myocarditis.

William Balass Yoakley, Wilmington, Ohio; Howard University College of Medicine, Washington, D. C., 1915; member of the Ohio State Medical Association; aged 63; died, July 9, of cerebral hemorrhage.

John Gerald Bowers, Muskegon, Mich.; University of Minnesota Medical School, Minneapolis, 1934; member of the Michigan State Medical Society; aged 31; was killed, July 8, in an automobile accident.

Henry Anthony Merkel * Wilmington, Ill.; University of Maryland School of Medicine, Baltimore, 1916; served during the World War; for many years health officer; aged 47; died, July 26, of heart disease.

Arthur Sanders Bean, Morrisville, Vt.; New York Medical College and Flower Hospital, New York, 1916; member of the Vermont State Medical Society; aged 63; died, July 23, of cerebral hemorrhage.

Frank Maurice Boonstra, Muskegon, Mich.; Rush Medical College, Chicago, 1929; member of the Michigan State Medical Society; aged 36; died in July of injuries received in an automobile accident.

Frank Winthrop Smith, Red Oak, Iowa; State University of Iowa College of Medicine, Iowa City, 1894; member of the Iowa State Medical Society; aged 68; died, July 6, of heart disease.

Joseph A. Sesta * Jersey City, N. J.; George Washington University School of Medicine, Washington, D. C., 1922; aged 43; died, July 21, in the Christ Hospital of cerebrospinal meningitis.

Edward Fyndoll Wright, Greenville, Texas; Memphis (Tenn.) Hospital Medical College, 1900; past president of the Hunt County Medical Society; aged 64; died, July 9, of heart disease.

James O'Dell Rhea, Linden, Ind.; Medical College of Indiana, Indianapolis, 1902; veteran of the Spanish-American and World wars; aged 63; died, July 30, of cerebral hemorrhage.

Waite Leonidas Lambert, Asheboro, N. C.; Jefferson Medical College of Philadelphia, 1921; formerly county coroner; aged 44; died, July 17, in Asheville of pulmonary tuberculosis.

Charles A. De Witt, Los Angeles; Bennett College of Eclectic Medicine and Surgery, Chicago, 1897; aged 69; died, July 7, in the General Hospital of a self-inflicted bullet wound.

John Tillman Mills, Sasakwa, Okla.; Memphis (Tenn.) Hospital Medical College, 1905; aged 72; died, June 13, in the Veterans Administration Facility, Muskogee, of senility.

Richard Vance Spencer, Chicago Heights, Ill.; University Medical College of Kansas City, Mo., 1907; served during the World War; aged 59; died, July 11, of pneumonia.

Millard Louys Beucler, Cincinnati; University of Cincinnati College of Medicine, 1925; aged 39; died, July 3, of amyloidosis of the liver and spleen, with osteomyelitis.

George D. Lezotte, Muscatine, Iowa; Rush Medical College, Chicago, 1881; member of the Iowa State Medical Society; aged 81; died, July 4, of cardiovascular renal disease.

Frederick W. McKnight, Mesa, Ariz.; George Washington University School of Medicine, Washington, D. C., 1909; aged 63; died in July of hypertensive cardiorenal disease.

Ernestine Julia Hicks Garl, St. Maries, Idaho; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; aged 79; died, July 6, of endocarditis.

Jacob Wickerham Davis, Hawthorne, Nev.; Physio-Medical College of Indiana, Indianapolis, 1889; aged 85; died, July 2, of hypertrophy of the prostate and uremia.

Daniel Fitz Randolph, Waldron, Ind.; Medical College of Indiana, Indianapolis, 1888; aged 84; died, July 13, of chronic myocarditis and acute dilatation of the heart.

Lewis Wilson Berry, Trego, Wis.; Indiana College of Medicine and Midwifery, Indianapolis, 1881; aged 89; died, July 19, of myocarditis and arteriosclerosis.

Herman Leo Nahin, Milwaukee; College of Physicians and Surgeons of Chicago, 1895; aged 73; died, July 4, of coronary thrombosis, arteriosclerosis and hypertension.

Antoinette J. Hutchings, Lodi, Calif.; California Medical College, San Francisco, 1896; aged 84; died, June 25, in a hospital at Stockton of arteriosclerosis.

Charles Edmond Verge, Quebec, Que., Canada; M.B. Laval University Faculty of Medicine, Quebec, 1904, and M.D. in 1906; aged 56; died, July 10.

Otho H. Witcher, Sweet Springs, Mo.; American Medical College, St. Louis, 1889; aged 68; died, July 11, of chronic nephritis, cystitis and prostatitis.

Owen County Rees, Stratford, Ont., Canada; Chicago Homeopathic Medical College, 1887; served during the World War; aged 73; died, July 28.

William Stowe Fowler, San Marino, Calif.; College of Physicians and Surgeons of Chicago, 1888; aged 81; died, June 5, of aortic stenosis.

James Henry Greenwood * Detroit; Detroit College of Medicine, 1894; aged 74; died in July of carcinoma of the prostate.

Granville Ralph Todd, Knoxville, Tenn.; Tennessee Medical College, Knoxville, 1908; aged 60; died, July 6, of heart disease.

Norman R. Henderson, London, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1895; died, July 15.

David Ford * De Soto, Mo.; Barnes Medical College, St. Louis, 1900; aged 64; died, July 16, of chronic myocarditis.

Francis Wesley Forge, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1919; aged 43; died, July 11.

J. F. Hartman, Glenville, W. Va. (licensed in West Virginia under the Act of 1881); aged 81; died, July 11.

John W. Graham, Early, Iowa (licensed in Iowa in 1886); aged 79; died, July 10, of cerebral hemorrhage.

ANIMAL EXPERIMENTATION IN CALIFORNIA

To the Editor:—Our attention has been called to a paragraph in an editorial which appeared in *THE JOURNAL*, February 19, which reads:

In 1932 and subsequently, a determined attempt was made to interfere with the use of dogs from the San Francisco pound, by the medical schools in the San Francisco Bay area. This attempt was frustrated by the combined vigilance of the medical profession and public health authorities.

From this quotation it must be inferred that the San Francisco pound was until 1932 providing dogs for use of medical schools; that an attempt was made to stop this practice, and that the attempt failed. Nothing could be further from the truth. As a matter of fact the opposite is true. Neither dogs nor any other animals have ever been provided by the San Francisco pound for medical schools. In 1932 an attempt was made to obtain dogs from the San Francisco pound for such purposes but it raised such a storm of protest that the matter was dropped. Incidentally it resulted in the addition of the following section to the pound ordinance:

SECTION 27. If the poundkeeper, or any one in his employ, shall knowingly sell or give any impounded animal to any person, firm, corporation, association, medical college or university of the state for the purpose of animal experimentation, the offender shall be guilty of a misdemeanor.

Any person, firm or corporation who, by or through fraud, misrepresentation, coercion or threat, induces any violation of the foregoing provisions, shall also be guilty of a misdemeanor.

This ordinance is in effect and has been since Sept. 27, 1932.

THE SAN FRANCISCO SOCIETY FOR THE
PREVENTION OF CRUELTY TO ANIMALS.
POUNDKEEPER.

CHARLES W. FRIEDRICH, S.,
Secretary and Manager.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

RAGWEED DESTRUCTION—DISTRIBUTION OF POLLEN

To the Editor:—1. Have any states or communities enacted laws requiring the destruction of ragweed? 2. If so, how successful have they been? 3. Have campaigns for the eradication of ragweed by the payment of a certain bounty per hundred pounds collected proved effective? 4. Has the expense of such campaigns been great? 5. In how close proximity to a field of pollinating ragweed must a person allergic to it be in order to be affected?

M.D., Massachusetts.

ANSWER.—1 and 2. As far as has been determined, no state or community has enacted a weed law specifically naming ragweed and requiring its destruction. Many states have laws covering a limited list of so-called noxious weeds the destruction of which is mandatory. Ragweed is listed as a noxious weed in some state weed bulletins but in such instances the term "noxious weed" is not construed as in the sense of mandatory destruction. At the 1937 session of the Illinois state legislature a definite effort was made by certain interested persons to have ragweed included in the list designated as noxious weeds. The legislature thought best not to include it because of the large acreage of ragweed and the consequent heavy burden that would be imposed on land owners. However, a resolution was passed requesting the governor to designate certain days in August as "Weed Destruction Days" and authorizing the director of the state department of agriculture "to consider the establishment of a comprehensive weed control program specifically to encourage the destruction of ragweed, horseweed, poison ivy, etc." Almost all states and municipalities have laws covering the control of weeds on highways.

The provisions of these laws are usually carried out, resulting in the mowing of all tall weeds, including ragweed, from once to several times a year on streets, alleys and highways. Many municipalities also have laws requiring owners of property, including vacant property, to keep all weeds under control. The laws empower the city officials to cut the weeds if the owner fails to do so and to charge the expense to the owner. Such laws, if properly enforced, would result in effective control of ragweeds within the limits of most cities. But these laws are rarely enforced.

3 and 4. As far as can be ascertained, only one community has dealt with the ragweed problem on the basis of payment of bounty. This city offered a small bounty for each bundle of fifty ragweeds. Less than \$1,000 had been appropriated for the purpose and the money was exhausted during the first two days of the campaign. From the record of pollen in the air in the city concerned, it was evident that no general benefit was obtained by the campaign. During one season \$165,000 was spent on weed destruction in one of our large cities with no appreciable effect on atmospheric pollen contamination. It is only fair to note, however, that in certain areas favored by natural barriers to pollen a judicious expenditure of money might result in effective control of air-borne ragweed pollen.

5. The effective range of pollen depends first on the acreage of the field from which it comes, the stage of development of the pollinating weeds, and such weather factors as rainfall, wind velocity and wind direction. One may be removed as much as 5 or 10 miles from any large area of ragweeds and still encounter large amounts of pollen dropping from the upper air. Tests have been made 30 miles from shore over Lake Michigan, where it was found that the atmospheric contamination was 75 per cent as much as was found at the same levels and at the same time over the adjacent land. Communities in wooded areas removed as much as 100 miles from agricultural areas enjoy freedom from atmospheric contamination of ragweed pollen when the wind is favorable, but when strong winds blow directly from the agricultural areas the air of such communities may be contaminated with more than enough pollen to cause symptoms in ragweed sensitive persons. It must be remembered that because of convection currents the concentration of pollen in the upper air is fairly constant from the ground to heights of from 4,000 to 6,000 feet.

CONVULSIONS AND HIRSUTISM: DIAGNOSIS

To the Editor:—A woman aged 30 has had attacks of convulsions for the past five years limited to the legs and lasting from twenty to sixty minutes. She also has the feeling that her tongue is large and dry and will block her throat. She feels an attack coming on for many hours before it arrives. She had seven or eight attacks in the first two weeks, following which she was free from them for four or five months. During the attacks she lost 10 to 15 pounds (from 4.5 to 7 Kg.). She has a moderate degree of hirsutism; the thyroid gland has enlarged and she now has a medium sized goiter. After thorough examination, including examination of the nervous system and the blood sugar and the Wassermann test, the diagnosis of epilepsy was suggested but treatment gave no results. The administration of parathyroid extract and calcium was effective: the attacks stopped and the patient gained weight and felt better. Every time she stops, the attacks reappear. The administration of iodine did not influence the illness. Although the attacks are less frequent and the convulsive movements are slight, they come more quickly and the patient seems to be psychologically affected. At present she is receiving parathyroid extract and calcium twenty days a month and iodine the other ten days. Any suggestions for further study or treatment would be appreciated.

M.D., Quebec.

ANSWER.—The patient described presents an interesting but confusing diagnostic problem. The regional convulsions suggest a lesion in the brain. Further evidence for this may be found in the difficulty in swallowing, and the sense of choking from blockage in her throat. Although there is an aura of presentiment long before the attack there is no loss of consciousness that might be expected if this were typical epilepsy. Calcium is a definite though mild sedative, and hence the improvement that the patient obtained from the use of calcium is not necessarily specific.

Among conditions that should be considered are (1) adenoma of the pituitary gland, (2) tumor of the adrenal gland (suggested by the hirsutism), (3) gastric tetany with achlorhydria and faulty absorption or utilization of calcium, (4) idiopathic hypoparathyroidism and (5) primary brain tumor.

There is a considerable literature on each of these conditions. While not entirely typical or pathognomonic of any of them, the symptoms described could be caused by any one of these conditions under certain circumstances. Additional studies that should be made would include:

1. Determination of the blood serum calcium and phosphorus. Consistently high blood serum calcium and low inorganic phos-

phate would suggest an adenoma of a parathyroid gland. Blood calcium of less than 9 mg. per hundred cubic centimeters or higher than normal phosphorus would suggest hypoparathyroidism.

2. A dextrose tolerance test, since the utilization of dextrose is definitely disturbed in some cases of pituitary adenoma or adrenal tumor.

3. Determination of the gastric acidity.

4. Roentgenograms to show the sella turcica.

If the results are compatible with a presumptive diagnosis of adrenal tumor, the adrenal glands may be visualized by injecting air in the perirenal space just before taking a flat plate roentgenogram of this region. Without any evidence of hyperthyroidism, such as would be indicated by a higher than normal basal metabolic rate, iodine medication would seem to be contraindicated, since the large goiter may be largely colloid and cystic, producing less than the normal body requirement of the internal secretion of this gland rather than in a state of hyperactivity. The combination of parathyroid extract and calcium may be merely affording palliative relief from the effects of an organic lesion which should be located and identified.

INSOMNIA AND BAROMETRIC PRESSURE

To the Editor:—An attorney, highly intelligent and honest, states that for several years about twenty-four to twenty-eight hours before a rain he has severe insomnia, which he has at no other times. I have tested him and he predicts a rain accurately every time. Have you any suggestions?

DAN TUCKER MILLER, M.D., St. Louis.

ANSWER.—Many people, as well as wild and domestic animals, exhibit this increased excitability and irritability of the nervous system as low pressure storm centers are approaching and the air temperature and humidity rising. Susceptible persons often awaken in the quiet of the night for no apparent reason other than a sudden fall in barometric pressure. Little is known of the physiologic changes behind these disturbances in central nervous system function. There are hints that a real tissue swelling occurs as outside pressures are reduced and the cells imbibe free water from their surrounding medium (much as does a sponge). Many people have a severe headache, which is relieved as soon as the pressure begins to rise again. Some others with sclerotic changes exhibit a distinct tendency to convulsions and unconsciousness during periods of rapidly declining pressure.

Close investigation under carefully controlled conditions is needed in this field, for violent fluctuations in central nervous function do seem to come with the storm pressure changes. No way has yet been suggested for obviating these pressure disturbances in susceptible individuals; in truth, no such studies have even been undertaken. Petersen's volumes on "The Patient and the Weather" indicates somewhat the direction such studies should take, although they do not answer the question at issue. The only direct therapeutic suggestion to be made is that people thus susceptible to weather changes carefully abstain from central nervous system excitants, of which the most effective in common use is caffeine.

ELECTROCARDIOGRAPHIC LEAD 4 F IN CORONARY THROMBOSIS

To the Editor:—What are the diagnostic electrocardiographic features of lead 4 F in cases of coronary thrombosis? M.D., Arizona.

ANSWER.—If lead 4 F is taken with the polarity recommended by the special committee of the American Heart Association, that is, so that upward deflections in this lead represent positivity of the precordial electrode, the changes that are diagnostic of anterior myocardial infarction are as follows:

Soon after the thrombosis takes place definite elevation, of the S-T segment, usually 3 mm. or more, appears. This upward displacement is due to acute muscle injury and ordinarily disappears within a period of from two to three days after the occlusion. Before the S-T junction has returned to the isoelectric line, inversion of the T deflection at the end of the elevated plateau usually begins to occur and after from a week to ten days large sharply inverted T waves are present. The inverted T waves may persist for several months but eventually disappear.

In addition to these changes in the final ventricular deflection, important alterations in the QRS complex are seen with anterior infarction. The initial upward or positive deflection seen normally in lead 4 F disappears and the entire QRS group may consist entirely of a downward (Q) wave. This type of change is usually present when the infarct is large. If the infarct is small or if the apical lead is close to the edge of the infarct,

W shaped QRS complexes may be found. The modifications of the QRS group are due to the loss of functioning muscle in the heart and are, as a rule, permanent.

It should be emphasized that the changes in the precordial lead just outlined are caused by infarction of the anterior wall of the heart. Infarction of the posterior wall produces no characteristic QRS changes in such leads. In the early stages S-T segment depression is seen, and this finding, if marked, may be of diagnostic help. Later on large sharply upright T waves appear. Chest leads are obviously of limited value when posterior myocardial infarction is present.

BACKACHE SYNDROME: OBER'S SIGN

To the Editor:—Please explain the occurrence of Williams' and Ober's eponymic signs with relation to pain low in the back. If the original source is available, please give the reference.

HAROLD F. ROBERTSON, M.D., Philadelphia.

ANSWER.—Williams did not originate a specific sign or test as an aid to diagnosis of lesions causing pain low in the back. He has accurately described the symptoms and has evolved a logical theory which offers an explanation of the symptoms of the backache syndrome. He believes that the etiology of the lumbosacral and sciatic pain may be found in the degeneration or destruction by injury or disease of the intervertebral disk between the fifth lumbar vertebral body and the sacrum. This results in settling of the fifth lumbar vertebra on the sacrum, with a transfer of body weight back to the articular facets, which may subluxate, narrowing the foramina through which the fifth lumbar nerve roots emerge.

Most of the patients described by Williams have an exaggerated lumbar curve, a sacrospinalis muscle spasm and a fixed downward tilt of the pelvis. Ober's sign is positive when this fixed pelvic obliquity is associated with, if not actually due to, a shortened iliotibial band.

A description of Ober's sign and of the diagnostic observations reported by Williams may be found in the following references:

Williams, P. C.: Lesions of the Lumbosacral Spine, *J. Bone & Joint Surg.*, 19: 343-363, 690-703 (April) 1937.

Ober, F. R.: The Role of the Iliotibial Band and Fascia Lata as a Factor in the Causation of Low-Back Disabilities and Sciatica, *ibid.* 18: 105-110 (Jan.) 1936.

TRANSMISSION OF SYPHILIS

To the Editor:—Many cities now require that food handlers, beauty parlor operators, barbers and others have a certificate from a physician stating that they are free from any contagious or infectious disease, including syphilis. A patient who was treated for syphilis ten years ago with three courses of arsenic and mercury now has a positive blood Wassermann test, a positive spinal fluid and a paretic colloidal gold curve. Neither the wife nor the two children have any evidence of syphilis. Can I fill out the required blank and is there any possibility of the patient's transmitting syphilis?

M.D., Illinois.

ANSWER.—It is not likely that a person who has had syphilis for ten years could transmit it to another person either through sexual intercourse or by any professional act in the food handling or beauty parlor occupations. It would therefore be perfectly permissible, so far as syphilis is concerned, to sign a certificate that the patient is free from any contagious or infectious disease. Such regulations as those cited, singling out food handlers, beauty parlor operators and barbers, with the requirement that they be free from syphilis, is an excellent example of misguided public health hysteria.

IRRADIATION FOR HYPERTHYROIDISM

To the Editor:—What is the status of the application of radium to the neck for the cure of toxic goiter? Has it been used much with good results?

E. C. BAYLEY, M.D., Lake City, Minn.

ANSWER.—In disorders of the thyroid gland it is customary to consider the application of radium and the use of x-rays as the same form of treatment; namely, irradiation therapy. In certain instances, such as toxic adenoma, radium is thought to be superior to the x-rays, but in toxic goiter and hyperthyroidism the results by the two methods are fairly comparable.

Menville (*Radiology* 18:568 [March] 1932) reports data collected from thirty-eight states and seventy-five radiologists. The average of these results show 66.22 per cent of the patients cured and 21.07 per cent improved. Other reports show as high as 90 per cent of cures. Cure, according to Menville, means complete freedom from symptoms for a year following the cessation of therapy. One report (Groover, T. A.; Christie, A. C.; Merritt, E. A.; Coe, F. O., and McPeak, E. M.: Roentgen Irradiation in the Treatment of Hyperthyroidism, *The*

JOURNAL, May 25, 1929, p. 1730) reports that 97.37 per cent of the patients were either cured or markedly improved.

In a recent review of the subject, Jenkinson points out that the percentage of cures remains the same but that fewer patients are reporting for irradiation. He believed this to be due to the improvement in surgical technic until he found that fewer patients were being subjected to surgery in the larger clinics. It would seem that hyperthyroidism is, at least temporarily, on the wane.

The results of irradiation reported by radiologists certainly compare favorably with the results obtained by any other method. It should be remembered that the results obtained by irradiation are more time consuming than those obtained by surgery and, in addition, that the application of radium for this purpose is a highly technical procedure and should not be undertaken by any one who is not thoroughly familiar with the method.

POSSIBLE LEAD POISONING FROM TOOTH PASTE TUBES

To the Editor:—On examination of tooth paste tubes, an oxide of lead is noted to the extent of discolored tooth paste ejected from the tube. When the lining is rubbed with a clean cloth, black oxides are found on the cloth. Would it be possible for a patient who is exposed to these oxides over a long period of time to contract lead poisoning? A tube with a lining prepared by a celluloid varnish which consists of amyl acetate and equal parts of acetone and celluloid prevents this oxide from penetrating the paste.

H. L. KERR, M.D., Crane, Mo.

ANSWER:—If the tube in which tooth paste is enclosed is made of lead, there may be a small amount of lead dissolved in the paste (Danckwortt, P. W., and Siebler, G.: *Zur Toxikologie des Bleis und seiner Verbindungen*: III. Bleihaltige Zahnpasten, *Arch. d. Pharm.* 265:424-426 (May) 1927). If the tube is tin lined, or otherwise adequately protected, there is no lead absorption by the paste. It is possible that some such technic as that suggested might work effectively. However, one cannot be sure that the "discolored tooth paste" referred to is due to a contamination of lead unless it is so shown by chemical analysis. The amounts of lead found in tooth pastes by Danckwortt and Siebler were not large, and when one thinks what small quantities of tooth paste are used it appears most unlikely that a toxic amount could be obtained from this source. Most tooth pastes are now put up in tin lined tubes.

SENSATION IN ULNAR NERVE FROM IRRIGATION OF SINUS OR FROM MULTIPLE SCLEROSIS

To the Editor:—A man had a mild retrobulbar neuritis, diagnosed by characteristic changes in the visual fields; a chronic bilateral ethmoiditis seemed to be the cause. A submucous resection and left middle turbinectomy was done. As part of the after-treatment, the nose was irrigated with warm saline solution. The patient states that while the nose is being irrigated there is a sensation of warmth in the right arm along the course of the ulnar nerve, from the elbow to the wrist. The first time the nose was irrigated he thought that some of the solution was leaking and running down the forearm, because the temperature felt the same as that of the solution in the nose. Can you explain this phenomenon? Before the operation he complained of occasional numbness and dull pain in both arms and legs. This, however, has now subsided.

E. CLARENCE KERN, M.D., Montclair, N. J.

ANSWER:—There is no generally accepted explanation to account for the sensation of warmth in the right arm along the course of the ulnar nerve from the elbow to the wrist when the nose is irrigated. A possible pathway for such a reflex would be through the fifth nerve from the nose, down the descending branch to the level of the eighth cervical segment and out along the eighth cervical root to the inner side of the forearm. So far as is known, however, no such reflex phenomenon has ever been described. A much more simple explanation would be based on direct pressure on the ulnar nerve by the patient on the arm rest of the chair during the process of irrigation, setting up a mild phenomenon such as is commonly spoken of as one's arm "going to sleep."

The history of the case, however, suggests there may have been a mistaken diagnosis. Retrobulbar neuritis, particularly in a young person, is often the first symptom in multiple sclerosis and is seldom the result of ethmoiditis. Occasional numbness in both arms and legs, plus the sensation complained of along the course of the ulnar nerve, would be consistent with a diagnosis of multiple sclerosis. Other signs, such as changes in the deep reflexes, loss of abdominal reflexes, a history of some dysfunction of the vesical sphincter or attacks of unexplained fatigue should be sought. The finding of a first zone reaction in the colloidal gold test of the spinal fluid would be an additional factor pointing toward a diagnosis of multiple sclerosis.

BODY ODOR

To the Editor:—A professional man, aged 64, always in good health, with normal blood, urine, blood pressure and serologic reaction, has not had the slightest trace of perspiration odor until recently. He was one of those fortunate persons who literally never needed to take a bath, although, being of cleanly habits, he bathed frequently. For several years he has had a senile tremor which is not parkinsonian in character. In the last two months he has been troubled by a peculiar penetrating body odor. This is not noticeable in any particular region; it is subtle and not particularly unpleasant but hard to describe. It is possibly like burned bacon or sulfur. The patient is much troubled about his condition; he is a national figure, and although accustomed to meeting people he is now afraid to because of it. The basal metabolism is normal, there is no hyperidrosis and the condition seems to be a pure bromidrosis. Have you any suggestions?

M.D., Illinois.

ANSWER:—Bromidrosis is defined as a fetid or foul smelling perspiration. It may be localized or generalized and is usually associated with hyperidrosis. This case does not seem to show these characteristics. Assuming that the odor has been noticed by the physician and is therefore not an olfactory neurosis, is it strong enough to force itself to the attention of those not especially looking for it? The fact that the patient fears to meet people because of the odor suggests a neurotic state or obsession, and every effort should be made to overcome this fear. If it is an obsession neurosis, the following is suggested: explanation of the mechanism of obsession—that is, false interpretation of a normal sensation; encouragement of daily bathing; some sedative like sodium bromide to be taken twice a day. Examination of the blood is also suggested. It is possible that a 1 or 2 per cent solution of salicylic acid in alcohol as a sponge to the axillae and feet and after bathing a talcum powder containing salicylic acid would help. In view of the fact that the odor "is not particularly unpleasant," it might be possible for an expert in perfuming to make up a perfume for the powder which would cover the odor.

EFFECTS OF LIGATION OF SPLENIC ARTERY

To the Editor:—A white woman aged 64 was operated on for a large cyst of the tail of the pancreas. During the difficult delivery of the base of the cyst, the splenic artery was injured and had to be ligated proximally and distally. The patient made an uneventful recovery. What is known about early or late effects of ligation of the splenic artery?

M.D., Panama.

ANSWER:—The effect of ligation of the splenic artery is the same as the effect of splenectomy. Complete atrophy of the organ will take place, as the splenic artery is the sole arterial supply. In the absence of the spleen other organs assume some of its functions with practically no harm to the individual. Wiggers (Physiology in Health and Disease, ed. 2, Philadelphia, Lea & Febiger, 1937, p. 335) states that splenectomized human beings "live with a more limited reserve, i. e., they are less likely to survive acute hazards of everyday existence which involve decrease in oxygen supply."

BISMARSEN IN SECONDARY SYPHILIS

To the Editor:—A white woman, aged 23, began treatment for syphilis early in the seropositive phase of the secondary stage. She has received continuous treatment to date consisting of seventeen intravenous injections of neoarsphenamine (0.6 Gm.) and twenty-one injections intramuscularly of bismuth salicylate in oil (2 cc., or 0.12 Gm. of bismuth). She has just completed a course of bismuth injections and the blood Wassermann reaction is now negative. I have found it increasingly difficult to introduce neoarsphenamine into her veins and feel that I must use some other method if arsenic therapy is to be continued in her case. Will bismarsen solve my problem? How often should it be administered intramuscularly and how long can it be so administered safely? Is it unwise to allow a rest period of four weeks at this time before I continue with intramuscular therapy in the form of bismarsen? M.D., Pennsylvania.

ANSWER:—No mention is made of how long the blood Wassermann reaction of this patient has been negative, nor is any mention made of results of examination of the spinal fluid after lumbar puncture. One would be in a far better position to advise if these data were furnished. The Cooperative Group has recommended a minimum of twenty injections of an arsenical and of a heavy metal preparation given in continuous form of administration for secondary syphilis. If the lumbar puncture is negative, it might be recommended that the patient be given intramuscular injections of bismarsen, an initial dose of 0.1 Gm. in 1 cc. of sterile distilled water with two or three drops of 2 per cent solution of butyn and then 0.2 Gm. of bismarsen prepared similarly twice a week for the succeeding twenty weeks, this to be followed by a succeeding course of injections of bismuth subsalicylate, and then a repetition of both of these courses. If the blood Wassermann reaction continues to remain negative, it might be safe merely to keep the

patient under observation, a blood Wassermann test being made every three months for the first year and thereafter every six months for two years. There should be a searching physical examination at the discontinuance of therapy, including a cardiovascular check-up. The patient should be examined carefully every year thereafter. If the patient is married, she should of course receive continuous alternating courses of arsenicals and of bismuth throughout each pregnancy.

HEADACHES AND HYPOGLYCEMIA

To the Editor:—A man who seems to be suffering from hypoglycemia has headaches which come on a short time before meals. They are relieved to a certain extent by the use of sugar or other easily assimilated carbohydrates. The sugar tolerance curve parallels normal at a lower level. The headache was relieved by a hypodermic injection of 0.5 cc. of ergotamine tartrate, which was tried as a diagnostic measure. Do you have any information to assist in working out this case or in successfully treating it?

M.D., Calif.

ANSWER.—There is not sufficient detailed information in the query to form a basis for specific suggestions. In general the diagnosis of spontaneous hypoglycemia as a cause of symptoms must be based on the finding of an abnormally low blood sugar level at the time of the symptoms, and the relief of those symptoms by the administration of carbohydrate. The dextrose tolerance curve and the hyperglycemic response to administration of epinephrine have also been used as criteria, but the results of these tests are too variable to be conclusive (Lukens, F. W., and Ravdin, I. S.: *Am. J. M. Sc.* 194:92 [July] 1937). The relief obtained from the administration of ergotamine tartrate is not especially helpful unless one can show that this relief is obtained without the increase in blood sugar which often follows its administration.

The rather constant low blood sugar levels found in endocrine disturbances, such as Simmond's disease and Addison's disease, rarely are accompanied by characteristic hypoglycemic symptoms. Hypoglycemia due to liver disease is more fluctuating and is more apt to cause symptoms (Judd, E. S.; Kepler, E. J., and Ryncarson, E. H.: *Am. J. Surg.* 24:345 [May] 1934). Hyperplasia, adenoma or carcinoma of the islet cells of the pancreas causes hypoglycemic symptoms but cannot be distinguished from liver disease unless other evidence of liver deficiency or of abdominal tumor is obtained.

Although other methods have been advocated, the most effective medical treatment for hypoglycemic symptoms appears to be a high carbohydrate diet with frequent feedings. If this treatment is not effective, if endocrine disease can be ruled out and liver disease is not apparent, and if the severity of the symptoms warrants it, an exploratory laparotomy is indicated.

DOUCHES AFTER MENSTRUATION

To the Editor:—What is the attitude of the medical profession toward young girls who are virgins taking a douche after every menstruation? This question arose in a physical culture class in a college and I could not say what the doctors in general practice or the gynecologists would say on the matter.

M.D., Massachusetts.

ANSWER.—There is absolutely no justification for advising young girls who are virgins to take douches after menstruation. First of all it is entirely unnecessary and secondly it may result in injury in some cases and masturbation in others. The vagina is perfectly capable of cleansing itself of menstrual blood without artificial aid. Even for women who are not virgins there is no necessity to take douches except for some specific reason.

LYMPHANGIO-ENDOTHELIOMA AND HYPERNEPHROMA

To the Editor:—I recently operated on a boy aged 11 and removed a tumor about 6 cm. in diameter from the second left intercostal muscle. The pathologic report was hypernephroma. Twenty months previously the same child was operated on and a tumor mass removed from the left triceps muscle. The pathologic report of that tumor was lymphangio-endothelioma. The patient has no subjective or objective urinary manifestations which might lead one to suspect any adrenal or kidney involvement. Are these two types of tumors related in any way and may one have a hypernephroma with no involvement of the kidneys or adrenals, such as may arise from adrenal rests?

JOSEPH D. ROMINO, M.D., Fairmont, W. Va.

ANSWER.—Lymphangio-endothelioma and hypernephroma are in no way related, although it is possible to confuse the two histologically in atypical cases. Adrenal rests are not as common as has been generally supposed. Lubarsch found eight adrenal rests in the kidney in 300 necropsies. It is difficult to find any authentic reports of hypernephroma arising in adrenal rests outside the kidney.

ARTIFICIAL MENOPAUSE AT 51?

To the Editor:—A woman in her fifty-first year is menstruating regularly, observing closely a twenty-eight day schedule. Physical examination is negative. She is in good health and admits it. Is it considered good practice to give this patient a series of irradiations in order to stop menstruation?

M.D., Kansas.

ANSWER.—There appears to be statistical evidence that women who have a late menopause are more likely to develop adenocarcinoma of the body of the uterus and also carcinoma of the breast than women who cease menstruating before the age of 50. Hence some gynecologists and surgeons believe that a late menopause, especially after 50, is a warning of a tendency to malignancy and that adequate treatment should be given to stop the aberrant endometrial activity. Since at the present time this can be accomplished satisfactorily only by means of radium, roentgen rays or operation, it is inadvisable as a routine procedure.

DILATATION OF INTESTINE BELOW OBSTRUCTION

To the Editor:—Can dilatation of the intestine below an obstructive lesion be adequately explained on a physiologic basis? I had such a case recently in which the obstruction was due to postoperative adhesions in an adult. The question arose as to whether or not we were dealing with a megacolon, since the part of the intestine presenting the dilatation was the sigmoid and rectum. However, a biopsy showed no thickening of the bowel wall.

M.D., Illinois.

ANSWER.—There is no physiologic basis for a dilatation of the intestine below an obstructive lesion. If a stricture or continued spasm of the rectum can be ruled out, the most likely diagnosis in this case is a megacolon.

SEXUAL EXCITEMENT AND NERVOUS SYSTEM OF WOMEN

To the Editor:—Does lack of sexual excitement and orgasm have any effect on the nervous system of a normal woman who is menstruating regularly? On that of a normal woman who is not menstruating and who is going through the menopause? What is the best treatise in short form on such matters?

M.D., South Carolina.

ANSWER.—A large number of women go through their entire lives without experiencing any sexual excitement or orgasm. These women may bear children just as do other women and their general health may be good. Many physicians claim, however, that sexual satisfaction is important for the complete physiologic and nervous adjustment of women. Lack of libido probably has no deleterious effect on women who are in the menopause. Interesting books on this subject are those by:

Dickinson, R. L., and Beam, Lura: *A Thousand Marriages*, Baltimore, Williams & Wilkins Company, 1931.
Stekel, Wilhelm: *Frigidity in Woman in Relation to Her Love Life*, New York, Boni & Liveright, 1925.
Gallichan, W. M.: *Sexual Apathy and Coldness in Women*, Boston, Stratford Company, 1928.

PROCAINE HYDROCHLORIDE FOR SPRAINS

To the Editor:—In *THE JOURNAL*, August 13, page 646, appears a query captioned "Injection of Procaine Hydrochloride for Sprains." A physician from California asks "Is it considered good practice to inject procaine hydrochloride into a sprained knee as routine treatment? An osteopath nearby is doing this in order that children may continue to play basketball." The answer categorically negatives the advisability of this procedure. *THE JOURNAL* has repeatedly featured this method, first sponsored by Professor Leriche of Strasbourg. Your Paris correspondent under date of Sept. 20, 1933, in *THE JOURNAL* Nov. 4, 1933, states that the medical profession is indebted to Professor Leriche of Strasbourg for the treatment of sprains by injection of procaine hydrochloride. In *THE JOURNAL* Jan. 13, 1934, page 148, appeared the communication of Dr. Ralph R. Fitch not wholly favorable to the method. This elicited the correspondence of Dr. J. C. Weissman published in *THE JOURNAL*, March 3, 1934, page 714, correcting Fitch's misapplication of the method, followed by the correspondence of Dr. R. E. Logan (*THE JOURNAL*, April 7, 1934) supporting Weissman. Then again your regular Paris correspondent under date of April 18, 1934, gives a supplementary report of Leriche's method. The article on immediate treatment of articular traumatisms, by Arnulf and Frieh (*Presse méd.* 42:597 [April 14] 1934, abstr. *THE JOURNAL* June 23, 1934, p. 2150) confirms Leriche's practice. *THE JOURNAL* June 4, 1938, page 1936, contains a lengthy abstract of Professor Leriche's article which appeared in the *Presse médicale* June 12, 1937. Having assiduously followed the teachings of Leriche, may I state that my own experience is wholly at variance with the advice of the commentator. The injection of procaine hydrochloride has been repeatedly applied by me with satisfaction for the relief of painful joint injuries (bandaged or not, splinted or taped) of basketball, baseball and football players of the teams of the College of the City of New York, whom I serve in the capacity of surgeon. Equally successful has been its use in the more exacting patients of private practice.

MARTIN W. WARE, M.D., New York.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in *The Journal*, October 1, page 1319.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An affiliate of the American Board of Surgery. New York, Oct. 21-22. Sec., Dr. Paul M. Wood, 745 Fifth Avenue, New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral.* St. Louis, Nov. 11-12. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written examinations will be held in various parts of the United States, Oct. 17 and Feb. 20. Application for the February examination must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, Nov. 5 and Feb. 4. General oral, clinical and pathological examinations for all candidates (Groups A and B) will be given in St. Louis, May 15-16. Applications must be filed not later than sixty days prior to date of examination. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: St. Louis, May 15. Applications must be filed before February 15. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Memphis, Tenn., January. Applications for this examination must be filed with the Secretary on or before Oct. 15. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF PEDIATRICS: Detroit, October 26; Rochester, N. Y., November 13; and Oklahoma City, November 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 28-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF SURGERY: Part I will be given simultaneously in various centers throughout the United States, Oct. 10. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: New York, Jan. 13-15. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Louisiana June Report

Dr. Roy B. Harrison, secretary, Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, June 2-4, 1938. The examination covered twelve subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and fifty-seven candidates were examined, 155 of whom passed and two failed. Eighteen physicians were licensed by reciprocity. The following schools were represented:

| School | PASSED | Year Grad. | Per Cent |
|--|---|--------------|----------|
| George Washington University School of Medicine..... | (1936) | | 78.5 |
| Louisiana State University Medical Center..... | (1937) | 78.7, 80.3,* | |

Kentucky June Examination

Dr. A. T. McCormack, secretary, State Board of Health of Kentucky, reports the written examination held at Louisville, June 8-10, 1938. The examination covered eleven subjects and included 110 questions. An average of 70 per cent was required to pass. Eighty candidates were examined, seventy-nine of whom passed and one failed. The following schools were represented:

Hawaii July Examination

Dr. James A. Morgan, secretary, Board of Medical Examiners, Territory of Hawaii, reports the oral and written examination held at Honolulu, July 11-14, 1938. The examination covered ten subjects and included eighty questions. An average of 75 per cent was required to pass. Five candidates were examined, two of whom passed and three failed. One physician was licensed by endorsement on June 1 after an oral examination. The following schools were represented:

Book Notices

Hearing: Its Psychology and Physiology. By Stanley Smith Stevens, Ph.D., Department of Psychology, Harvard University, Boston, and Hallowell Davis, M.D., Department of Physiology, Harvard Medical School, Boston. Cloth. Price, \$4.50. Pp. 489, with 166 illustrations. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Limited, 1938.

A formal review of this work would in all likelihood not do it justice. Nothing quite like it has appeared in English or for that matter in any foreign language. Here the otologist may recognize with full force the invasion of the field of hearing by physiologists, psychologists and physicists; he may see what exact methods, such as audiometry, have added and see what the vacuum tube, borrowed from the radio, has done in the hands of Wever and Bray and their followers to tell the story of hearing. A glance at chapter headings in this work and a comparison with similar material in standard textbooks of otology will make clear what great changes the past few years have brought. Where will one find, in even advanced textbooks on ear diseases, whole chapters devoted to such topics as the nature of the auditory impulse and the sensitivity of the ear, and pages devoted to the nature of pitch, loudness and other attributes of sound as well as to the character of auditory localization? Investigation in the field of hearing dormant for many years now borrows from the purer sciences and takes advantage of advances in what may seem to be unrelated fields. Those men who effected the revolution in medical training in this country thirty odd years ago and who insisted that the future doctor needed the widest type of scientific education are vindicated. How many otologists would have thought a generation ago that to understand why a patient does not hear he would need to remember how to use the logarithmic tables and the calculus of college days? Every earnest otologist must possess this book and read it. It will not remain the last word on its subject; the authors themselves would be the first to admit this, but, such as it is, it is the most significant signpost to the future in the field of audition in many years.

An Introduction to Clinical Perimetry. By H. M. Traquair, M.D., F.R.C.S., Ophthalmic Surgeon, Royal Infirmary, Edinburgh. With a foreword by Norman M. Dott, M.B., Ch.B., F.R.C.S. Third edition. Cloth. Price, \$9. Pp. 320, with 230 illustrations. St. Louis: C. V. Mosby Company, 1938.

Since his Middlemore Essay on perimetry in 1920, Traquair has become the champion and evangelist of the new third dimensional perimetry, which considers defects in the visual field in relation to the size of the stimulus object. This quantitative concept, which considers not only extent but intensity, was introduced by Bjerrum in his study of glaucoma and elaborated by Roenne. The present general acceptance is largely due to the concise and vigorous exposition in Traquair's textbook, which has become recognized as a modern classic in ophthalmology. The present revision maintains the same format as the original edition, but besides changes in the text it contains fifty-six more pages, sixty-three more figures, two additional colored plates and an enlarged bibliography. The new illustrations are principally from clinical records and aptly elucidate and emphasize the subject matter. By his systematic use of a few white test objects, graduated in size, the depth of a visual defect is mapped in the same manner as altitudes are shown by contour lines. Reduced illumination and color testing aid in searching for defects of very slight intensity and for studying the quality of relative defects. The field for red, 10/300 (10 mm. object at 300 mm. distance), should approximately equal that for white, 10/2,000. If this proportion holds, the condition is generally stationary; but if the red field is markedly smaller, the "disproportion" indicates an actively progressive process. If the quantitative perimetric test is repeated from time to time, slight variations in function are readily discerned. The transition between the defect and the seeing field may be gradual or abrupt, that is, the margin of the scotoma may be "sloping" or "steep" a characteristic of proved significance in diagnosis and prognosis. Tobacco amblyopia is featured by the presence of one or two areas of greater intensity within the scotoma. Even in women who may hesitate to admit an excessive use of tobacco, the demon-

stration of these typical "nuclei" enables a diagnosis to be made with confidence. In retinal detachment, the defect for blue is more intense than that for red, producing a true interlacing of the color fields. In glaucoma, the worse the field, the worse the eye. Traquair advises operation even when fixation is threatened, unless the field as a whole is extremely contracted. He diagnoses rhinogenic retrobulbar neuritis only when sinus disease is evident. In his discussion of acute retrobulbar neuritis he includes toxic amblyopia, Leber's disease, neuromyelitis optica and meningo-encephalitis. The perimetry of disorders of the optic chiasm is considered in detail and divided into lesions of the anterior angle, body and posterior angle. He accepts the conclusions of Cushing and Percival Bailey that temporal lobe tumors tend to present the characters of tract hemianopia, the defect appearing in the nasal field of the eye on the side of the lesion. He believes that the sparing of the fixation area in hemianopic lesions is adequately accounted for by the double vascular supply of the nerve elements concerned with the macula in both the external geniculate body and the visual cortex. Traquair utilizes simple, non-mechanical apparatus and stresses the fact that the most important work in perimetry has been done with the simplest instruments. He still holds that the elaborate refinements of the Ferree-Rand instrument have not yet been proved to be of special value in clinical work, while their utilization entails the serious disadvantage of prolonging the time required for examination. The most expert perimetry can be done with a simple arc perimeter of from 250 to 330 mm. radius and a Bjerrum screen for use at 2 meters. The object should be moved from the blind to the seeing area, as the patient's fixation is thus less likely to be deflected. No routine is advised, but a flexible procedure by which the essential character of the field changes are determined with the minimum fatigue to the patient. Quantitative perimetry has shown that the power of recovery in both the photochemical apparatus and the nerve fiber is extremely high. In almost all forms of interference with the visual path, the tendency to recovery on removing the cause is a prominent feature. The volume charms by its simplicity, satisfies by its thoroughness, and every one seriously interested in ophthalmology or neurology should be familiar with its contents.

Yours to Venture: A Book About Your Future. By Robert B. Updegraff. Cloth. Price, \$2. Pp. 214. New York & London: Whitelley House, McGraw-Hill Book Company, Inc., 1937.

This is an interesting, challenging book. The thesis is well expressed in the title. The author sees about him a changing world in which new values are replacing the old and in which each individual can find or make a niche for himself, provided only he finds out what he can do best, is willing to venture forth on confidence in his analysis of that ability, and prepared to give of his best, including free "sampling" of his ability, for the reward which he desires. The author believes that in order to get what one desires one must first know what that desire is—in his own terms, one must write a "specification" for one's future in definite terms and then go about fulfilling the specification. He divides individuals not into groups of employers and employees or into doctors, lawyers, merchants, mechanics, farmers, vice presidents or advertising managers but into classes characterized by such descriptive terms as "noticers," "finishers," "specification-writers," "organizers," "salvagers," "seers," "crystallizers," "creators," "inventors," "entertainers," "protectors and comforters" and "packagers." This seems to be an attempt to reduce vocational guidance to a relatively simple and practical formula based on the personal characteristics of the individual. This is, of course, the accepted method, but this book puts it in a new and interesting manner. One may not share the author's optimism when he declares, in effect, that there is a ship for every one to venture in and a reward for all who have the courage to venture, but he may still recommend this book as stimulating reading, even though it fails to get down to any especially practical details. It will undoubtedly stimulate the secretion of the "acid of discontent" which is supposed to be the spur to action, and for those who need just that stimulus it will be a good book. For those who already have the discontent but lack the other

qualities for success, the book may serve only to sink them deeper in the morass of despair, because it makes hard things seem too easy. Physicians, after a careful reading of the book, may choose to recommend it to some of their patients who require psychotherapy, but to some other patients they would undoubtedly not wish to suggest it. The self-rating scale which is found on the reverse of the jacket would be disapproved of by many modern mental hygienists on the ground that it favors unwholesome introspection; most persons might use it for their own amusement, amazement, or possibly more serious self analysis, without harm.

Climate and Acclimatization: Some Notes and Observations. By Sir Aldo Castellani, K.C.M.G., D.S.C., M.D., Professor of Tropical Medicine, Louisiana State University, New Orleans. Second edition. Cloth. Price, 10s. Pp. 198, with 17 illustrations. London: John Bale, Sons & Curnow, Ltd., 1938.

Castellani's book, which was first published in 1930, now appears with, as the author states, "some minor alterations and additions." In view of the fact that Castellani has been inspector general of the Italian military and civil medical services during the Ethiopian war—in association with which there has followed his elevation as count of Kisumaio—he has undoubtedly been very busy, certainly too busy to rewrite the book, which, rather sketchy and inadequate in the first place, is still sketchy and inadequate and reflects a ten year lag. One of the real difficulties with books on climate of the type of Castellani's is the limitation of the discussion of climate to the effects of the tropical climate on northern man. It would almost seem that an interest in the effects of the climate of the higher latitudes must await some adventurous son of the tropics exiled to the north. If tropical air is important for life in the tropics, the variable air of the north might seem equally important for life in the tropical zone. Castellani actually recognizes this in his introductory statement: "Chalmers and I, while recognizing the paramount role played by parasites and hygienic conditions, have persistently endeavored to emphasize the fact that climate per se also plays an important part, and recently there have been signs in various quarters tending to show that the importance of climatic factors is again going to be generally recognized." For the physician interested in a cursory survey of the effect of tropical climate, Castellani's book will be of use; actually, however, the advance in meteoropathology has been rapid since the World War and this advance must be followed in the current literature. Unfortunately widely scattered in journals quite divergent in their particular field of interest—physiology, aeronautes, meteorology, biometrics, engineering—this material is not considered in the new edition. Fortunately an effort has recently been made to assemble a complete bibliography of the entire field by the Committee on Air Conditioning of the American Medical Association, and this bibliography is now available to the interested American investigator.

Die Röntgentherapie. Unter Mitarbeit von Fachgenossen zusammengestellt von Professor Hans Holfelder, o. ö. Professor für allgemeine klinische Röntgenkunde an der Johann-Wolfgang-Goethe Universität, Frankfurt a. M. Paper. Price, 27 marks. Pp. 341, with 265 illustrations. Leipzig: Georg Thieme, 1938.

The present work is the result of a collection of papers given at the yearly postgraduate course at the Institute of Radiology in Frankfurt on the Main. It is presented under the editorship of Dr. Holfelder and gives an interesting view on the modern methods of roentgen therapy as they are practiced in this institute. A valuable article by Engelmann on the microscopic changes of the pathologic and normal cell after the application of the various methods of irradiation distinctly increases the value of the book.

The textbook is divided into two parts. The first division contains, among other contributions, a review of the physical and biologic problems of the modern methods of roentgen and radium therapy. There is also a chapter on the clinical treatment during and after irradiation, on the treatment of the exposed skin and on studies of the erythema of the skin. The legal aspect of damage to the skin is briefly discussed by Holfelder. The contributors are, besides Holfelder and Engelmann, Holfelder's collaborators (Reisner, Weiswange, Teschen-dorf, Toepfner, Engels and Burkin). Based on the saturation method of Pfahler, the workers developed as the result of many years of experience and through studies of the biologic

problems the present method at the institute of high voltage therapy, which consist in decreasing fractional doses with slow increase of the intervals. Examples of the applied rhythm of administration are given by many tables. Numerous photomicrographs illustrate Engelmann's observations on the pathologic and normal cell exposed to short courses and long courses of irradiation. The latter was administered by the protracted fractional method (Coutard). He concludes that the selective power of rays is increased by the time factor and not by the wavelength. He illustrates this factor by mentioning the Choul therapy, which, though employing rather long wavelengths, results in high efficiency when administered over a long period. He furthermore found when comparing the length of administration that though the protracted fractional method does not damage the connective and muscular tissue it nevertheless more readily endangers the bone marrow and endocrine glands than does the short course. Hence the radiologist should select the proper method for each case. Reisner, whose studies on the erythema of the skin are well known by previous publications, emphasizes again the importance of the rhythm of administration and the selected single dose.

The second division gives in detail the method and results in treatment of cancer of the skin, tongue, pituitary gland and breast, and branchiogenic and esophageal carcinoma. This part is closed by chapters on the treatment of thyroid diseases, Hodgkin's disease and bronchial asthma. The results obtained compare favorably with those of other clinics in Europe and the United States. Nothing as yet can be said of Holfelder's recent method whereby he shortens the time of each single sitting by increasing the roentgen minutes to 90 and the milliamperes to 10. He found the short duration of the sitting especially useful for his method of "compressed irradiation," which, in Holfelder's opinion, is necessary for a better effect on the focus itself. Crossfire and tangential administration of rays are further means of avoiding unnecessary damage.

On the whole, the book is a fundamental description of the method of irradiation practiced in the Institute for Radiology in Frankfurt. It is well written and abundantly illustrated with reproductions of photographs and photomicrographs. Though the methods of irradiation in high voltage roentgen therapy are still changing, this book is a valuable aid for every one working in the field. By its suggestion of careful selection of the dose and rhythm of irradiation, more desirable results may perhaps be obtained with minimal injury of healthy tissue.

Physiological and Clinical Chemistry. By William A. Pearson, Ph.C., M.D., Ph.D., Professor and Head of the Department of Chemistry and Physiological Chemistry in the Hahnemann Medical College and Hospital of Philadelphia, and Joseph S. Hepburn, A.M., B.S. in Chem., M.D., Associate Professor of Chemistry and Research Associate in Gastroenterology in the Hahnemann Medical College and Hospital of Philadelphia. Second edition. Cloth. Price, \$5.50. Pp. 467, with 46 illustrations. Philadelphia: Lea & Febiger, 1938.

These authors are well qualified to correlate biochemistry with clinical medicine, and this completely revised edition should prove useful not only as a textbook but also as a reference volume. The subject matter includes physicochemical principles and qualitative methods, a brief survey of organic chemistry and extensive discussion of the lipids, carbohydrates, proteins and enzymes. The chapters on foods and metabolism incorporate the various clinical, chemical and dietary aspects of this subject with a section on food poisoning. The clinical chemistry per se is carefully arranged so that the methods of examination of the various body fluids are arranged in separate chapters, the chemistry of each being discussed fully. There is an extensive chapter on milk and one on water analysis. Although clinical chemistry is not a standard course in most medical schools, such courses, although elective, do exist and this book should serve as a satisfactory reference work for such teaching. A medical student has no difficulty in correlating his pathology with his clinical medicine; clinical pathologic conferences serve that purpose. There is, however, in most curriculums no correlative course for chemistry, and the application of biochemistry to the clinical sciences is dependent, more or less, on the individual professor of medicine. For those sufficiently informed to seek such correlation, this book is especially recommended.

Pocket Atlas of Anatomy. By Victor Pauchet and S. Dupret. Third edition. Fabrikoid. Price, \$4. Pp. 368, with 345 illustrations. New York & London: Oxford University Press, 1937.

The present edition of this deservedly popular little book, though enlarged, is still a pocket atlas. There were 297 illustrations in the first and 325 in the second edition. The new ones show lymphatics, the solar plexus, relations of the thoracic viscera to the chest wall, and so on. The English edition is published by the Oxford University Press and was printed in Edinburgh. The nomenclature conforms with the Birmingham revision of the BNA. An index has been added. As a pocket companion it will always be interesting and will save many a "quart d'heure" which would otherwise be lost.

Tuberculosis Among Children and Young Adults. By J. Arthur Myers, Ph.D., M.D., F.A.C.P., Chief of Medical Staff and Director of Tuberculosis Activities, Lymanhurst Health Center. With chapters by C. A. Stewart, M.D., Ph.D., Clinical Professor of Pediatrics, University of Minnesota, and Paul W. Gessler, M.D., F.A.C.S., Assistant Professor of Orthopedic Surgery, University of Minnesota. An Introduction by Allen K. Krause, M.D., Lecturer in Medicine, Johns Hopkins University. Second edition. Cloth. Price, \$4.50. Pp. 401, with 71 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1938.

This edition contains many references to the newer knowledge concerning tuberculosis in the earlier years of life which has been developed since the first edition. Many chapters have been rewritten and others added. The book is divided into three parts, tuberculosis in infancy, in childhood and in young adult life. One chapter of the first part is devoted to recent advances in the knowledge of tuberculosis and the application of this knowledge in diagnosis, treatment and prevention. Another chapter contains a discussion of sensitization and immunity. Each chapter throughout the book is a concise presentation of the essential facts concerning the subject presented, and all phases of tuberculosis occurring in these age periods are ably presented. One chapter of the second part deals with chronic nontuberculous basal pulmonary diseases in childhood. In each part the subject matter of each chapter is at first discussed and at the end a comprehensive summary is given, followed by a list of references. This arrangement makes the book especially valuable for reference. While some of the opinions may be debatable, the book on the whole is a valuable addition to the literature on tuberculosis and should prove useful to all engaged in tuberculosis work.

Das Rheumabuch des Doctor Ballonius nach der Rheumaschrift des lateinischen Textes, Guilelmi Ballonii Liber de Rheumatismo et Pleuritide Dorsali, Paris 1642. Deutsch herausgegeben von Dr. Walter Ruhmann, Spezialarzt für innere Krankheiten in Berlin. Boards. Price, 1.80 marks. Pp. 70, with portrait. Mittenwald: Theophrastus-Verlag Arthur Nemayer, 1938.

This brochure contains a translation into German of the treatise on rheumatism by Ballonius, published in Paris in 1642. Ballonius, a French physician of the seventeenth century, was not the first to describe rheumatism; his monograph, however, is worth while because of the fine description it gives of rheumatic manifestations. The treatise is not an epoch making contribution but ranks well with the many books of the seventeenth century. In addition to Ballonius's paper, the translator gives a lengthy introduction and an index of the classic contributions to rheumatism throughout the ages.

Medizinische Chemie für den klinischen und theoretischen Gebrauch. Von a. o. Prof. Dr. K. Hinsberg, Vorstand der chemischen Abteilung des Patholog. Univ.-Inst., Berlin, und Dozent Dr. Dr. K. Lang, Stabsarzt, Leiter d. physiol.-chem. Abtlg. d. Militärärztl. Akademie, Berlin. Paper. Price, 18 marks. Pp. 458, with 61 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1938.

This book is a compilation of the methods used in medical chemistry. The authors state that it is not for beginners, an acquaintance with the various methods being assumed. The book is divided into an "inorganic" and an "organic" section. The original reference to each method, as well as a short criticism of the method, is given. A bibliography concerning modifications of the various methods is given at the end of each section. This volume is a good reference book for those interested in the procedures used in the clinical laboratory. Since, however, many chemical methods in medical chemistry are continuously being improved, one finds some of the methods already somewhat antiquated. For example, the preparation of the sample for lead analysis is too long and unduly intricate.

They use carbon tetrachloride as the solvent for dithizone. Chloroform is preferable because it is a better solvent for the dye and the lead dithizone complex is more stable in chloroform.

Lehrbuch der Differentialdiagnose Innerer Krankheiten. Von Professor Dr. M. Matthes. Fortgeführt von Professor Dr. Hans Curschmann, Direktor der Medizinischen Universitätsklinik in Rostock i. M. Elbich edition. Cloth. Price, 30 marks. Pp. 806, with 132 illustrations. Berlin: Julius Springer, 1937.

This edition merits continued praise as an excellent textbook of differential diagnosis. The presentation of the material is simple and well organized and the subjects differentiated appear in the page margins. The photographic illustrations are excellent. It is of interest that the author includes acute leukemia in the differential diagnosis of acute fevers. This is not usual in standard textbooks of medicine. From the clinical point of view the author is probably correct. The subject matter, whether an acute or a chronic disease, is extremely well differentiated. A condition as rare as arteritis nodosa as well as the common cause of headaches is presented. While the references to the literature are rather old, the author has not failed to mention some of the more recent important observations. The references to the American literature on the whole are scanty and in a few instances erroneous. Thus on page 587 Bagen is misspelled; on page 355, Levine and Boss should be Levine and Golden.

The Anatomy of the Domestic Animals. By Septimus Sisson, S.B., V.S., D.V.Sc. Revised by James Daniels Grossman, G.Ph., D.V.M., Professor of Veterinary Anatomy in the College of Veterinary Medicine, The Ohio State University, Columbus, Ohio. Third edition. Cloth. Price, \$12. Pp. 972, with 770 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

This book is concerned with the anatomy of the horse, ox, dog, pig and sheep, and to this edition has been added a section on the chicken. The book takes up first the skeleton of these domestic animals, then the joints, fascia and muscles, followed by comparative discussions of the digestive system, respiratory system, urinary and genital organs, vascular system, lymphatic system, nervous system and sense organs. It is well illustrated and should be of great use to persons interested in the anatomy of domestic animals. While the previous edition was published twenty-four years ago, the general plan and scope remain unchanged except for the new chapter on the anatomy of the chicken and the large increase in the number of new illustrations.

Kurzes Handbuch der Ohrenheilkunde. Von Dr. Hermann Marx, o. ö. Professor und Vorstand der Universitätsklinik für Ohren-, Nasen- und Kehlkopfkrankheiten, Würzburg. Paper. Price, 46 marks. Pp. 846, with 465 illustrations. Jena: Gustav Fischer, 1938.

In his preface the author states that this book is not written for the general practitioner or the student of medicine, nor is it a reference work for the experienced specialist. It is primarily intended for the beginning otologist and contains more or less what the author has been accustomed to impart to his assistants regarding the practice of this specialty. Its name belies its character somewhat. The title states that it is a short handbook but the work and index comprise 846 pages. There are numerous illustrations, many of them beautifully colored. There are no particular excursions into the new. This textbook comprises the experience of a lifetime of teaching and can be used with great benefit not only by those for whom it was written but by others even more advanced in the specialty. Examination of the references to the literature cited by the author reveals, as has been stated on other occasions, that in the Teutonic countries there is a tendency to ignore nearly all contributions to the literature excepting their own.

Muir's Bacteriological Atlas. Atlas Enlarged and Text Rewritten. By C. E. van Rooyen, M.D., Halley Stewart Research Fellow and Lecturer in Bacteriology in the University of Edinburgh. Second edition. Cloth. Price, \$5.25. Pp. 90, with 83 illustrations. Baltimore: William Wood & Company, 1937.

This book, meant primarily for beginners in medical bacteriology, should be used in conjunction with a good textbook. The text in this edition has been rewritten and twenty-six new colored plates have been added. The illustrations are good and the legends accompanying them excellent. However, an atlas is no substitute for a good set of microscope slides.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals: Liability for Defective Equipment.—The plaintiff, aged 74 years, underwent an appendectomy at the defendant hospital. A special nurse, employed to attend him after the operation, learned from the anesthetist that the operating physician desired that the plaintiff be given a "tap water" proctoclysis, an instillation of tap water into the lower bowel, drop by drop. Equipment necessary for a proctoclysis consists of a container, a standard or stand which supports the container above the level of the bed, a rubber tube, a rectal drip, a catheter, and a screw clamp placed on the rubber tubing to regulate the flow. The equipment provided for and placed in the plaintiff's room consisted of a container, a rubber rectal tube and a spring clamp. The special nurse secured a standard and attempted to construct out of these articles the apparatus for proctoclysis. She filled the container with hot water and fastened it to the standard. Realizing then that the equipment was inadequate, she placed the end of the rubber tubing on the bed and went out to secure the other necessary articles, having fastened the spring clamp on the tubing to prevent any flow. In her absence the clamp came apart, allowing the hot water to drain from the container through the rubber tubing and onto the plaintiff's bed so that his back and thighs were severely burned. Because of a spinal anesthetic, the plaintiff was insensitve from the waist down and he did not realize what happened other than that he was warm. In an action against the hospital to recover damages for injuries sustained from the hot water burns the trial court gave judgment for the plaintiff, and the defendant appealed to the Supreme Court of Minnesota.

The plaintiff sought to hold the hospital liable on the theory that it furnished a defective spring clamp, which, because of its defective condition, caused the plaintiff's injury. The trial court correctly instructed the jury, said the Supreme Court, that the defendant could not be held liable for any act or omission of the special nurse; the defendant's liability, if any, must rest on the claimed breach of duty in failing to furnish an efficient clamp, resulting in the plaintiff's injury. One who furnishes an instrumentality for a special use or service impliedly warrants the article furnished to be reasonably fit and suitable for the purpose for which it is expressly furnished. The clamp involved in this case and the other articles present in the plaintiff's room were furnished by the hospital to be used for "customarily needed purposes where an important surgical operation has been performed." The arrangement with the hospital, the court thought, could be nothing less than the furnishing of necessary facilities and equipment for the efficient operation of its business. And these must necessarily be furnished for the particular purpose for which they are needed and designed. The hospital, however, strongly urged that this equipment, among which was the defective spring clamp, was not furnished for use in proctoclysis. The effect of that argument, the court observed, was that, since the use made was other than that intended, injuries arising therefrom are not attributable to any fault of the defendant. With that contention, however, the court found itself in disagreement. It is true that a spring clamp is ordinarily utilized in the administration of an enema where the purpose is to allow either a full flow of the solution or to cut it off altogether. On the other hand, in proctoclysis the solution is injected drop by drop, a result that can be had only by the use of a screw clamp which can be adjusted to increase or decrease the flow, or shut it off completely. The important thing as regards the intended use of the clamp is not the general treatment that is given but rather, and only, the particular function of the clamp in any treatment, i. e., to shut off liquid flow through rubber tubing. The defendant hospital, in the opinion of the court, should be held to be aware of the obvious nature of the use of a spring

clamp, which is the stoppage of the flow of a solution through a rubber tube conduit. And this is so irrespective of the particular treatment being given.

There was, in the opinion of the court, sufficient evidence to show that the clamp was discoverably defective. The effect of the verdict in the lower court was to establish the defendant's negligence. From the evidence the Supreme Court was not prepared to say, as a matter of law, that the defendant could not readily have discovered this defect if a reasonable inspection of the clamp had been made. There was some intimation that the injury was caused by the negligent conduct of the nurse. Her negligence, if any, may be considered, the court said, only in relation to the defective clamp. It was on that theory that the case was submitted to the jury, and the jury's verdict resolved that issue in favor of the plaintiff. The nurse, although a trained professional, could reasonably rely on the hospital's furnishing a proper clamp. The court agreed with the defendant that if the article furnished was obviously unfit for the use for which it was furnished and intended and the nurse used it in violation of the usual standards of due care of nursing practice, the defendant would not be liable for any injurious effects therefrom. But, the court said, the defect was not patent. The clamp was furnished apparently ready for use, and it was not the nurse's duty to examine into its mechanical parts for the discovery of possible defects.

The judgment of the trial court for the plaintiff was affirmed. —*Butler v. Northwestern Hospital of Minneapolis (Minn.)*, 278 N. W. 37.

Medical Societies: Expelled Member Must Exhaust Remedies Within Organization Before Appealing to Court.—The Scotts Bluff County Medical Society, a component society of the Nebraska State Medical Association, which in turn is a constituent association of the American Medical Association, early in August 1935 adopted a resolution declaring it a breach of professional ethics for any of its members to contract individually with county or state officials to render medical care to persons on relief. Weyrens, a member of a society who had opposed the adoption of the resolution, subsequently entered into a contract with certain county and state relief officials whereby he agreed to render medical care to relief clients. After the society had notified him that he had violated the resolution, he was present at a meeting in which the matter was considered and admitted that he had broken the rule and argued against applying it. He was then expelled from the society. He made no effort to appeal from the expulsion order to the councilor of the state association of the district in which he practiced or to the Council of the Nebraska State Medical Association, rights that he could exercise by virtue of the by-laws of the Nebraska State Medical Association. Neither did he make any effort to obtain a rehearing from the county society or reapply after the lapse of one year for membership in the county society, as he had a right to do under that society's by-laws. Instead, he petitioned the district court, Scotts Bluff County, to enjoin the society from depriving him of his rights as a member in good standing. The district court dismissed his petition and he appealed to the Supreme Court of Nebraska.

He complained among other things that he had not been given a trial in the expulsion proceedings. As such matters usually go, in such organizations, said the Supreme Court, he had all the trial then asked for or that was necessary. He was present. He admitted the infraction of the rule adopted and argued against applying it. Any other or further trial would be futile and was unnecessary under the circumstances. There are two reasons, continued the court, why the plaintiff cannot be restored by a court of equity to his position as a member of the local society. First: He has not exhausted his remedies by appealing from the order of expulsion. When he became a member of this voluntary, unincorporated society, he assented to the rules governing the society. Before he can have recourse to the court because of his expulsion, he must

comply with the reasonable and uniform rules of that society, provided they do not contravene the laws of the land or offend public policy. As was said by this court in *Crisler v. Crum*, 115 Neb. 375, 213 N. W. 366:

It is a general rule of equity that, when a member of a voluntary, unincorporated association is aggrieved or feels injured at any action taken by the officers or committees of the association, within the scope of their authority and pertaining to its affairs, and where the laws and rules of the association provide a means of redress, he should first exhaust the remedies provided by the laws and rules of the association before applying to the civil courts.

Secondly: The court refused the relief asked for, because no civil or property right of the plaintiff had been invaded by the disciplinary action of the Scotts Bluff County Medical Society. The fact that a hospital in Scotts Bluff had dropped the plaintiff from its staff as a result of the expulsion proceedings and that the plaintiff's ability to increase his income had been reduced by that action did not, in the opinion of the court, constitute any invasion by the society of a civil or property right of the plaintiff. The hospital was not a party to this action but the evidence showed that one of its rules required the members of its staff and physicians serving the patients therein to belong to the county society. The plaintiff knew this rule and took the consequences when he knowingly and deliberately violated the rule set up by the county society. If the hospital chooses it may change its rule. As it now stands, this rule of the hospital results in inconvenience and some loss of income to the plaintiff but this cannot be attributed to the county society as a deprivation of a property right of the plaintiff. The applicable principle, continued the court, is as follows:

"A court of equity will not inquire into the regularity or validity of disciplinary proceedings by a voluntary unincorporated association, not organized for profit, against one of its members, when no civil or property right of such member will be affected."—*Rogers v. Tangier Temple*, 112 Neb. 166, 198 N. W. 873.

For the reasons stated, the judgment of the district court dismissing the plaintiff's petition for an injunction was affirmed. —*Weyrens v. Scotts Bluff County Medical Soc. (Neb.)*, 277 N. W. 378.

Malpractice: Burns Attributed to Faulty Adjustment of Therapeutic Lamp.—The plaintiffs, husband and wife, sued the defendant, a physician, for burns sustained by the wife during a heat treatment administered by a nurse in the defendant's office. The trial court gave judgment for the defendant, and the plaintiffs appealed to the Supreme Court of Washington.

The complaint alleged that the nurse negligently permitted a hot lamp to come in contact with the patient's back by failing to keep proper control over the device. From the evidence it appeared that when the patient called at the defendant's office for a treatment she had with her her 6 year old daughter, who at the request of the patient remained in the room while the treatment was being administered. In subjecting the patient's body to the heat, a lamp, to which was attached a cord plugged into an electric light socket, was moved back and forth over the patient's body. The patient testified that, at the time she was burned, the nurse had been regulating the heat and had treated her for some time. Finally the nurse pulled the electric plug from the socket but continued distributing the heat from the lamp over the patient's body. While she was so engaged, according to the patient's testimony, the office telephone bell rang and the nurse placed the lamp on some portion of the appliance and started to leave the room. As she was going out, the hot lamp dropped on the patient's back, inflicting the burns. The nurse, on the other hand, seemed to place the blame for the accident on the patient's little girl. The girl, however, testified that she had not touched the lamp and that when the accident occurred she was sitting in a chair reading a book. The patient also testified that the child did not touch the lamp. On appeal, the plaintiffs argued that the trial court had erred in instructing the jury that if they found that the accident was occasioned

by the act of the little girl the defendant was not liable, that the instruction given by the trial court withdrew from the jury the question of fact as to whether or not the defendant and his nurse were negligent in leaving the treatment room while the 6 year old child was in there, the nurse knowing that the child was likely to tamper with the lamp during the nurse's absence. But, said the Supreme Court, nowhere was it alleged that the defendant's negligence consisted of failing to watch the patient's 6 year old child and prevent the child from injuring her mother. The plaintiffs' theory of the case was that the nurse made some adjustment in the lamp and started to leave the room and that, because the device was improperly adjusted, the lamp dropped on the patient's back. If the plaintiffs desired, the court continued, to adopt as an alternative theory the story told by the nurse and then contend, contrary to her complaint and all of the testimony introduced in support of her case, that the child had upset the lamp, and that nevertheless the defendant was still liable for negligence on the nurse's part in not restraining the child, certainly the plaintiffs should have asked for a supplementary or qualifying instruction properly presenting this theory of liability on the part of the defendant. Instead of so asking, the plaintiffs simply excepted to the instructions given. Furthermore, it was admitted that the young child was taken into the room where the treatment was administered, at the request of one of the plaintiffs, the patient. The defendant had provided a place for the children of his patients, but the patient, as she testified, was nervous and wanted the child with her. Generally speaking, then, the plaintiffs could not base any claims against the defendant on the act of their own child. If because of the facts of this particular case a different rule might apply, the burden rested on the plaintiffs to see to it that such a question was submitted to the jury under proper instructions. Clearly from the evidence it could not be held, as a matter of law, that the defendant's nurse was responsible for the acts of the child.

The Supreme Court could find no error in the record, and the judgment of the trial court for the defendant was affirmed. —*Chapman v. Locr (Wash.)*, 76 P. (2d) 600.

- Western Surgical Association, Omaha, Dec. 2-3. Dr. Albert H. Montgomery, 122 South Michigan Blvd., Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Acute Pyuria Due to Dysentery Bacilli.—Dietrich encountered five cases of acute pyuria in which dysentery bacilli were isolated from the urine. Four of the cases are reported. It must be assumed that the dysentery organisms reach the urinary tract by the same route followed by the colon bacilli in cases of ordinary pyelonephritis. All the infections occurred in girls. An ascending infection of the urinary tract is suggested by the sex incidence. The symptoms in the cases cited were neither more nor less toxic than the symptoms of a similar infection due to colon bacilli. The recovery without treatment observed in case 1 and the improvement in case 3 prior to treatment suggest that, like a comparable infection due to colon bacilli, pyuria due to dysentery bacilli is usually subject to spontaneous remission. The urine promptly became sterile in two cases after an adult dose of ammonium mandelate. In the third case the occurrence of vomiting necessitated the omission of medication prematurely. Although the urine had cleared noticeably, the recurrence of frank pyuria and the persistence of bacilluria were observed after ammonium mandelate had been discontinued. After a second bout of fever the urine became sterile coincidentally with the administration of methenamine and ammonium chloride.

Convulsions Complicating Pertussis.—Habel and Lucchesi discuss the clinical features peculiar to convulsions occurring in forty-one of 516 patients with pertussis admitted to the Philadelphia Hospital from 1933 to 1936 and attempt to determine the causes and evaluate methods of combating them. The factors predisposing to convulsions included the age (less than 2 years) of the patient, the severity of the paroxysms, the presence of cyanosis, the presence of bronchopneumonia and

congenital defects of the brain. The convulsive state began with a period of somnolence during which the child was irritable when disturbed. The mortality rate for the series was 78 per cent, but for seventeen patients to whom transfusions were given the death rate was 35 per cent. In the majority of cases no specific pathologic change is present in the brain to point to an essential inflammatory cerebral disease as the etiologic agent; there are, rather, changes that may be attributed to an insufficient blood supply and to anoxemia. Clinically, convulsions usually occur in the spasmodic stage of the disease when the paroxysms are severe. This frequently results in venous congestion of the head and neck, with severe anoxemia. In patients having convulsions when pertussis is complicated by bronchopneumonia, cyanosis and inefficient circulation are instrumental in producing cerebral anemia and anoxemia. Since pertussis convulsions are most likely to occur during the whooping stage and to follow a paroxysm, any therapeutic measure that will reduce paroxysms to a minimum may be definitely considered a prophylactic agent. The various vaccines, given subcutaneously or intracutaneously, are advocated by many clinicians, as are also ether in oil (given by rectum), barbiturates and opiates. However, in the authors' experience convulsions have occurred even in patients receiving each of these remedies. They feel that cyanosis is a responsible causative factor; therefore, oxygen should be used early in all cases of bronchopneumonia and in infants having severe paroxysms even in the absence of bronchopneumonia. Once convulsions have begun, barbiturates should be given by mouth, by rectum or by the subcutaneous route. This should be supplemented with an immediate transfusion of whole blood and with the administration of oxygen (by means of a tent rather than by catheter). Tightly bandaging the extremities seems to help in a few cases. Attempts to overcome cerebral anoxemia should also include treatment to decrease the cerebral edema. Concentrated lyophilic normal human serum seems indicated, because theoretically it would dehydrate the cerebral tissue as well as increase the blood pressure and help to overcome vasomotor collapse.

Basal Metabolism in Nephrosis.—Farr performed thirty-four basal metabolism tests on eight children with the nephrotic syndrome. They showed no significant deviation from the expected metabolic rates, with one exception. In this case a slightly but consistently elevated rate was observed.

- Use of Cadaver and Animal Eyes for Training and Experience in Surgery. D. B. Kirby and J. P. Macnie, New York.—p. 904.

Diet, Vitamins and Cataract.—Yudkin favors the theory that attributes the formation of cataract to heredity and senility, local changes in the ocular tissue and general metabolic disturbances. There is some evidence to support the hypothesis that a vitamin deficiency may in many cases contribute to the onset of certain degenerative processes and manifestations of senility. It therefore is important to know what part the vitamins play in the maintenance of normal nutrition and health in the middle aged and the senile person (the person predisposed to cataract). Vitamin A plays an extremely important part in adult nutrition. It should be supplied in liberal proportion not only to youth during growth but in the food of the adult as well, if a good nutrition and a high degree of health and vigor are to be maintained. Vitamin B is responsible in part for the stimulation of appetite and "toning up" of the digestive mechanism. Recently it was suggested that it is in some way concerned in the metabolism of carbohydrate in the body. Vitamin G is essential to growth and to normal nutrition at all ages. When the food is poor in vitamin G for any considerable time, digestive disturbances,

nervous depression, general weakness and deterioration of tone and an unhealthy (or "unthrifty") condition of the skin are apt to develop; the incidence of infectious diseases seems likely to be increased, vitality diminished, life shortened and the prime of life curtailed by the early onset of senility. Vitamin C protects against capillary fragility and helps to protect the body from such changes as are characteristic of the aging process. In view of the present knowledge of human nutrition it is advisable that all elderly patients having any signs of early changes in the lens be instructed in nutrition.

Measles.—Top states that 27,430 cases of measles were reported in Detroit during 1935. Follow-up visits were made to every fifth family in which one or more susceptible contacts had not been reported as having developed measles in order to determine the accuracy of the history of previous measles and the number of cases which had not been reported. Analysis of age, sex, relationship of the period in the seasonal cycle to the secondary attack rate, relationship of the number of primary cases (1,253) per family to the secondary (1,380 secondary cases of 1,633 contacts) attack rate, the effect on secondary attack rates occasioned by repeated exposure to a constant intensity and the effect on secondary attack rates occasioned by one exposure to various intensities which might affect the secondary attack rate in a random sample of families resulted in the following conclusions: 1. The sex of the primary patient or that of the susceptible contact is unimportant. 2. Age of the primary patient may exert an influence on the secondary attack rate. Further investigation of this factor would appear desirable. 3. The age of the susceptible contact influences the secondary attack rate significantly. 4. Secondary attack rates are not greatly affected by the period

in the seasonal cycle in which measles first appears in the family. 5. The number of primary cases per family does not affect the secondary attack rate among the susceptible persons in the same family. 6. There is an additional hazard when a contact is exposed to measles a second time. 7. Intensity of exposure as measured by the number of cases in the family at one time does not appear to influence appreciably the secondary attack rate among the susceptible persons.

Resolving Lobar Pneumonia Simulating Tuberculosis.

—Of the various pathologic phases of pneumococcal pneumonia, the stage of resolution from a roentgenologic point of view has probably been least appreciated. The problem of differentiation between some cases of pneumonia and tuberculosis Cohen has encountered ten times; five cases are reported which illustrate especially instructive roentgenologic features of resolution of lobar pneumonia in adults. All had been incorrectly diagnosed at one time or another as tuberculosis. The error committed was that of faulty interpretation and evaluation of the roentgenograms of the chest, particularly of a single film. The points that the author discusses are the pathology of a normally resolving unilobar pneumonia, x-ray appearance of a normally resolving unilobar pneumonia, roentgenologic differentiation between resolving lobar pneumonia and tuberculosis, and factors in delayed resolution. For roentgenologic differentiation between the two diseases, the value of serial roentgenograms taken at short intervals is emphasized.

Radiation Treatment of Collum Cancer.—From 1919 to 1929 de Büben states that 702 cases of inoperable collum carcinoma were treated by irradiation at the Women's Clinic. There were 658 cases with an inoperable condition in which the uterus was fixed and the carcinoma invaded the neighboring tissues and forty-four of highly advanced and hopeless cases of inoperable collum carcinoma. From the standpoint of palliative effect 305 patients, or 43.1 per cent, showed primary healing. From the standpoint of complete cure, on a basis of at least five years with an absence of symptoms, thirty-eight patients were completely cured. According to the usual method of treating inoperable collum carcinoma, tubes containing 25 mg. of radium supplied with a primary silver-brass-lead filter are used. Usually 50 mg. of radium is used; the time of irradiation extends from twenty-four to forty-eight hours. If at all possible the vaginal radium treatment is completed with the intracervical method. For this purpose radium tubes with sterilized containers which are supplied with filters corresponding to a total of 1 mm. of platinum are introduced into the cervical canal after it is dilated. With the combination of the vaginal and cervical

methods, from 4,000 to 6,000 milligram hours is generally used. The treatment is distributed over several weeks. In the advanced cases of collum carcinoma in which the cervix cannot be reached without causing damage to the tissue, only the vaginal method is resorted to and consequently smaller doses of radiation are used than are employed in the combined method.

Tattoo Treatment of Anal Pruritus.—Hollander tattooed with mercuric sulfide the perianal skin of fifteen patients for severe chronic anal pruritus. This resulted in the relief of the itching and the return of the skin to a normal texture. Two patients have remained well for more than one year, three for more than six months and ten for less than six months. The duration of the symptoms previous to treatment ranged from two to seventeen years. In none of these cases was any rectal or constitutional disease found to account for the rectal itching. In five of the cases, after repeated scrapings of the fissured skin, segments of mycelium were seen on microscopic examination.

Dermatitis and Stomatitis from Amalgam Fillings.—Traub and Holmes have recently encountered two instances of dermatitis caused by the mercury of amalgam fillings. In the first patient a mild stomatitis was present. Such cases represent examples of contact dermatitis rather than of irritation of the skin and the mucosa resulting from the absorption of mercury from the amalgam fillings. From a review of the controversial literature on the subject of chronic mercurial poisoning resulting from amalgam fillings it is concluded that: 1. The danger to the patient of chronic mercurial poisoning from silver amalgam fillings alone is remote. 2. Chronic mercurial poisoning from copper amalgam is not frequent and is to be expected only in hypersensitive subjects. 3. Acute manifestations such as dermatitis or stomatitis are probably more common than is generally believed. 4. The degree of sensitivity to different preparations of mercury varies in individuals, nor does every person necessarily react to all mercurial compounds. The skin generally reacts more readily to the external application of mercury than does the mucous membrane.

Dermatophytosis of the Feet.—Berberian believes that the stockings of patients with ringworm are the commonest source of reinfection. Not only is the fungus found on stockings of patients suffering from the infection but it survives the ordinary process of laundering and is capable of growing in the fabric. His experiments show that *Trichophyton interdigitale* is capable of growth on different kinds of materials used as inner lining for shoes and also on wood, rock, moss and seaweeds. The use of all rubber slippers in gymnasiums and on beaches is recommended as a means of safeguarding one's feet against the possibility of infection or reinfection from

exogenous sources. The vapor of formaldehyde is an effective disinfectant against *Trichophyton interdigitale*. Its disinfecting action is greater and more rapid (six hours) when the article to be disinfected is moistened just before being placed in the disinfecting chamber.

Objective Tinnitus Aurium.—Bredlau reports three cases of objective tinnitus and reviews similar cases described in the literature. Objective tinnitus may be either vascular or muscular in origin. Spasmodic contractions of the eustachian tube are the chief causative factors in the muscular type of objective tinnitus; the immediate cause is the separation of the moist surfaces of the eustachian tube. Hysteria and neurasthenia have been hypothesized as predisposing or contributing factors. The vascular type of tinnitus is caused by the preternatural transmission of arterial or venous impulses to the ear by (1) aneurysms, including arteriovenous aneurysms, both intracranial and extracranial, (2) hypertension, (3) vascular tumors of the brain and the ear, (4) coarctation of the aorta, (5) severe anemias, (6) pregnancy, (7) acute inflammatory disease of the ear and (8) vasomotor and endocrine disturbances.

Bronchial Asthma and Nasal Allergy.—Ramirez regards bronchial asthma as a clinical entity and defines it as a bronchial neurocellular syndrome characterized by recurrent attacks of paroxysmal dyspnea. He divides asthma into two large types, (1) broncho-edematous and (2) bronchospastic. The broncho-edematous type, in which there is edema of the bronchial mucosa, includes asthma due to sensitization to an allergen. Truly non-allergic asthma due to remote stimulation by some other excitant, such as a pathologic condition of the nose, the effects of heat and cold or emotion, manifests not broncho-edema but bronchospasm. Therefore in most cases in actual practice the condition is of a mixed type pathologically, even though etiologically it belongs fundamentally to one type. In diagnosis, statistics on heredity in allergy are undependable. There are many pitfalls in sensitization tests. For example, a physician with seasonal asthma had negative reactions to cutaneous, ophthalmic, passive transfer and inhalation tests in the nose. However, he reacted immediately to the inhalation of ragweed pollen directly into the lungs. The average patient requires care from both the allergic and the nonallergic angle. Satisfactory results will not be obtained merely by eliminating offending allergens or by attempts at hyposensitization. The pathologic condition must be corrected surgically. There is no doubt that many patients with sinusal involvement are allergic and should not be operated on. The bronchospastic type of asthma resulting from remote reflex stimuli originating in the nose or the accessory sinuses obviously will not be benefited except by elimination of the local pathologic condition. In cases of broncho-edematous asthma in which sensitization has taken place a gross nasal pathologic condition must be corrected surgically if lasting satisfactory relief of symptoms is to be expected; this, of course, must be in addition to proper treatment from an allergic standpoint. Grains of pollen embedded in the lining membrane of the antrums and possibly of the other sinuses may in this way be responsible for the continuance of symptoms in highly sensitive persons after the particular pollen has disappeared from the air of the locality. The author believes that there is a definite relation of endocrine dysfunction and vitamin

deficiency not only to asthma but to allergy in general. He does not think that any one gland or a deficiency in any one vitamin is solely responsible. Any gland or combination of glands may be an important factor affecting the underlying fundamental mechanism of hypersensitivity. This phase of allergy indirectly may involve a strong hereditary influence and determine the shock tissue.

Vitamin D in Acne.—Maynard reviews 255 cases of acne treated since 1930. Of these, 123 patients were treated by means other than the use of viosterol and 132 with viosterol; eighty-six were treated with the roentgen ray. The dietary instructions and the local applications were identical in the two groups. Of those receiving viosterol the dosage was started at 20 drops each morning; in many the dosage was later increased to 40 drops. The reason for the morning dose was to take advantage of the influence of sunlight on the synthesis of vitamin D in the skin. Of the eighty-six patients treated with roentgen rays the acne was better in thirty at the end of three months, in thirteen it was much better and in twenty-six the condition was healed; and of the 132 patients treated with viosterol the respective numbers were eight, twenty and thirty-two. There were twenty-one relapses in the first group of patients against one in the second group. The percentage of satisfactory results at the end of three months was 48 in the roentgen group and 75.6 per cent in the viosterol group.

Single Doses of Sulfanilamide.—Lucas took 15, 30 and 45 grains (approximately 1, 2 and 3 Gm.) of a commercial sample of prontosil at intervals of about two weeks. The drug was taken for experimental purposes. The drug was taken by mouth, with about 150 cc. of water, one hour after a light breakfast. Samples of blood and total urine were collected for analysis at intervals of one hour for six hours following the ingestion of the drug. The blood was again

examined twenty-four hours after the sulfanilamide was taken. The urine was collected and analyzed after eight, ten, twelve, twenty-four and forty-eight hours. Following the largest dose (45 grains) the forty-eight to seventy-two hour urine was also collected and a final specimen was collected on the fourth day. Only mild ill effects were noted following the ingestion of any of the doses of sulfanilamide. A feeling of considerable fatigue began about six hours after each of the two larger doses was taken but it was not severe enough to necessitate any curtailment of usual activities. Slight hyperesthesia followed the largest dose, about ten hours after the drug was taken, and it was in the form of a mild formication; during the following day a slight tingling sensation about the face and finger tips was present. The concentration of sulfanilamide in the blood was not directly proportional to the dose. Blood concentrations of sulfanilamide above 5 mg. per hundred cubic centimeters are not easily attained (while liver and kidney function are normal), since conjugation and excretion occur rapidly. The proportion of sulfanilamide which undergoes conjugation is not constant.

Percutaneous Tuberculin Reaction.—Wright and his colleagues employed an ointment for the percutaneous test by absorbing old tuberculin with fullers' earth and then adding enough hydrous wool fat to make an ointment. On a quantitative basis, 1 cc. of old tuberculin required 1 Gm. of fullers' earth and 2.25 Gm. of hydrous wool fat. Prior to application of the ointment the skin of the selected site on the chest over the sternum was cleansed with ether and then a small portion of ointment (about the size of half a dry pea), was rubbed into an area about the size of a fifty cent piece (30 mm.). Sixty revolutions with the finger were taken as an arbitrary standard. A rubber finger cot was worn on the finger. Within twelve hours, 73 per cent of forty-four tuberculous patients tested showed pale or pinkish papules, either alone or with surrounding zones of erythema and the skin induration on the site of ointment application. After twenty-four hours there was a distinct reaction in 94 per cent and after forty-eight hours 100 per cent of the patients had reacted positively. The papules, which are a distinctive feature of the skin reaction, varied in number from ten to twelve to more than 100 in different cases. In a general way, those patients who were known to be most allergic from their intradermal tests gave the most marked percutaneous reactions but there were enough exceptions to render this impression only tentative. The percutaneous test was checked in the general medical wards. All patients there receive a Mantoux test as part of their routine investigation. A positive percutaneous reaction was obtained in only three cases, which coincided exactly with the observations on routine intradermal injection of 0.1 cc. of old tuberculin. In all, fifty-seven general ward patients were examined in this manner. A control ointment containing the same amount of fullers' earth and hydrous wool fat but no old tuberculin was also used on all the patients tested in the general medical wards. Two patients with negative Mantoux reactions showed small areas of slight erythema on both test and control sites. These disappeared after thirty-six hours. No papules, which seem to be the distinctive feature of the positive percutaneous reaction, were present. The cheapness of ointment testing, together with its stability, warrants more intensive application of the percutaneous test by physicians and others interested in detecting early cases of tuberculosis in childhood. As a case finder outside hospitals the percutaneous test with tuberculin ointment has a definite field of usefulness.

Sulfanilamide and Venereal Lymphogranuloma.—Shropshire gave sulfanilamide orally to nine patients with rectal stricture due to venereal lymphogranuloma. All patients presented a strongly positive reaction to the Frei test and had been under observation for periods varying from one to three years prior to the administration of sulfanilamide. Most of the patients had previous treatment in other institutions. With one exception, all patients received 30 grains (2 Gm.) of sulfanilamide daily in three divided doses for fifteen days. One patient was unable to tolerate sulfanilamide in excess of 20 grains (1.3 Gm.) daily but was given the same total amount over a period of twenty-three days. No other treatment, local or general, was administered. Following this treatment a rest of from seven to ten days was given, after which sulfanilamide was again resumed. Some patients responded more rapidly than others, and the number of periods of treatment varied with the individual response. In five cases the tenesmus, mucous stools, rectal discharge and bleeding completely disappeared under therapy. Two patients with rather extensive involvement of the rectum are still under treatment because of the presence of occasional mucous stools, although the other rectal symptoms have disappeared. The most striking effect of treatment was the rapid improvement in appetite accompanied by an increase in weight and strength. Colostomy had previously been performed in other institutions on two patients. One patient did not suffer from rectal symptoms but complained of a constant, profuse, purulent discharge from the sinus of the left inguinal colostomy, associated with bleeding and frequent evacuations from the transverse colostomy. These symptoms rapidly improved following the administration of sulfanilamide. The other patient was debilitated and complained only of a profuse, rectovaginal, sanguinopurulent discharge, which greatly diminished under treatment and lost its bloody character. These encouraging results prompted the use of sulfanilamide in the treatment of inguinal and vulval types of involvement. To date, only three male patients with inguinal adenitis due to venereal lymphogranuloma have been treated. Sulfanilamide was found to influence this type of involvement favorably but

it failed to cause the adenitis to subside completely. One female patient with chronic ulcers of the vulva, hypertrophic vulvitis and chronic urethritis due to venereal lymphogranuloma has shown definite improvement on sulfanilamide therapy, with prompt response of urinary symptoms and gradual healing of the ulcers. As yet there has been no change in the elephantiasis edema of the vulva.

*Influence of Tonsillectomy on the Course of Rheumatic Fever and Rheumatic Heart Disease: Study of 108 Cases. W. B. Allan and J. W. Baylor, Baltimore.—p. 111.

Tonsillectomy and Rheumatic Fever.—Allan and Baylor studied 108 persons with rheumatic fever who had been subjected to tonsillectomy and adenoidectomy. Of the 108 cases, ninety have been followed from ten to twenty-three years and eighteen from one to ten years. The follow-up period of sixteen of the latter group was terminated by the death of the patients. The average age of the eighty-six living patients was 26.4 years in 1935. The eleven patients followed for from one to five years had recrudescences, three single and eight multiple. All the patients in this group died from rheumatic cardiac disease. Fifteen patients were followed for from six to ten years; eight had recrudescences, four single and four multiple. Five of these patients died; two deaths were due to rheumatic cardiac disease, one to tuberculosis, one to erysipelas and one to peritonitis following an appendectomy. Twelve of the thirty-six patients followed for from eleven to fifteen years had recrudescences, three single and nine multiple. There were two deaths in this group, one from rheumatic cardiac disease and one from nephritis. Thirty patients were followed for from sixteen to twenty years and of these twelve had recrudescences, four single and eight multiple. There were three deaths in this group, two from cardiac disease and one from drowning. Of the sixteen patients followed for from twenty-one to twenty-three years four had recrudescences, two single and two multiple. The single death in this group was due to acute rheumatic fever with pancarditis. Since rheumatic cardiac disease developed in only six of the forty-nine rheumatic patients not having cardiac involvement at the time of operation, it is concluded that tonsillectomy and adenoidectomy are to be recommended in the treatment of rheumatic fever. The incidence of persistent infection of the nasopharynx was considerably higher in the patients who had recrudescences than in the entire group. Recrudescences were common in the first five years after operation. Most of the patients who had repeated recrudescences during this period died of rheumatic cardiac disease. Rheumatic cardiac disease occurred more frequently in patients having recrudescences, and deaths from rheumatic cardiac disease occurred only in this group.

Lowered Resistance to Pneumonia.—Nungester and Klepser discuss a possible mechanism by which exposure to cold, alcoholic intoxication or deep ether anesthesia may lower the resistance of a person to pneumonia. Mucin injected intra-bronchially favored the production of pneumonia in rats sprayed one day later with pneumococci. Certain factors, such as exposure to cold, prolonged deep ether anesthesia or alcoholic intoxication, increased the aspiration of mucous material placed in the nose of rats. Such factors also increased the incidence of pneumonia if pneumococci and mucin were previously inoculated intranasally. Cold or alcoholic intoxication were found to interfere with the closing of the glottis, thereby permitting the aspiration of mucin and pneumococci.

Clinical Significance of Eosinophilia.—Kirk states that if eosinophilia was the result merely of chemotaxis there should be a quantitative relationship between the active agent and the eosinophilia. He has not been able to find this correlation in

the cases of scarlet fever, pemphigus and secondary syphilis. Except for Chillingworth's experiments there is little to be said for the vagal stimulation influence. Holden was able to produce "eosinophils" at will in specimens of urine by altering the pH before centrifuging the white blood cells down and staining them. He suggests this alteration in the pH of the blood, resulting from the induced hyperpnea, as an explanation for Chillingworth's experiments unless these cells were identified by supravital technic, a point which is not mentioned in the original paper. Digitalis intoxications could be equally well explained on a drug sensitivity basis, such as probably occurs in nirvanol medication. Until the true function of the spleen is elucidated, the influence of the spleen on eosinophilia will remain problematic. An allergic basis for eosinophilia seems most likely, the strongest points being the inability to reproduce it by a single injection of foreign protein, and the similar time relationship between the production of eosinophilia and the known production of allergy. There is no postfebrile rise in eosinophils in the cases of typhoid. The reduction is of possible diagnostic significance. The eosinophilia in trichinosis and pemphigus has apparently no prognostic significance.

Prostigmine Test in Myasthenia Gravis.—In clinic and office practice the long period of observation formerly used by Schwab and Viets is both impractical and unnecessary. They therefore modified the prostigmine test so that it can be completed in one hour. The best objective symptom for evidence of improvement is determined; for example, degree of ptosis, ability in swallowing, talking, or the muscular strength as measured by ergograph or dynamometer. Three 1 cc. ampules (3 cc.) of prostigmine, to which 0.01 grain of atropine sulfate has been added, is injected intramuscularly. Thereafter at intervals of ten minutes, for an hour, the degree of objective improvement is noted in one column, grading as follows: 0 no improvement, 1 slight improvement, 2 moderate improvement, 3 considerable improvement and 4 complete or marked improvement. In a second column, with the same grading, the patient's subjective opinion of the improvement is scored, giving value to a general feeling of well being. The figures in the two columns are added and the total score is obtained. The maximal score is forty-eight. If the total value is less than eight the test is negative and it is extremely unlikely that the patient has myasthenia gravis. If the total value is from eight to eighteen the test is doubtful and it should be repeated or a therapeutic trial of oral prostigmine should be tried. If the score is more than seventeen (from eighteen to forty-eight) the test is positive. This is presumptive evidence of the diagnosis of myasthenia gravis. In general, the two columns are similar and parallel each other to a striking degree. The test has been used in thirty-five cases of myasthenia gravis, with a score of twenty-five or more. No patient with myasthenia gravis gave

a negative test. In ten the tests were repeated with practically no change in the scores. Owing to the marked change in symptoms of patients with myasthenia gravis after an injection of prostigmine, some observers feel that the need of scoring by making several observations is unnecessary. This is true, perhaps, in three fourths of the myasthenia cases, but in the non-myasthenic group, particularly in chronic cases, suggestion plays a large part and they may score high enough on the subjective symptoms to make the diagnosis of myasthenia possible unless several tests are made. In diseases that simulate myasthenia gravis, negative prostigmine tests were obtained.

Stray Radiation.—Braestrup made measurements to establish the relationship between the stray radiation and the type as well as the amount of protection provided in different high voltage x-ray installations using similar operating conditions. A description of the instruments used is given. Under normal operating conditions all the investigated enclosed tube holders provide sufficient protection to the patient. The term ray proof, which at present generally is applied to tube heads, is somewhat ambiguous. None of the measured tube heads permit routine manipulation with safety while the x-ray tube is excited although the shutter is closed. More effective shielding of the direct radiation is essential in cases in which it is desired to operate the tube continuously and have the shutter control the timing of the treatments. It is suggested, therefore, that the term ray proof be limited to tube enclosures from which the stray radiation does not exceed 0.036 roentgen per hour at 1 meter focal distance in any direction and with the tube operating at its normal rating. Tube enclosures with less shielding but still providing ample protection to the patient could then be described as x-ray protective or radiopaque if the stray radiation does not exceed 1 roentgen hour under the foregoing conditions. Measurement of stray radiation from the different installations indicates that a high factor of safety can be obtained at a much reduced cost if greater consideration is given to the arrangement of the protective materials. Several cases of insufficient protection were corrected as a result of this survey.

Roentgen Treatment of Plantar Warts.—Popp and Olds determined the effect of roentgen treatment of ninety-one patients with plantar warts. These patients came from a distance and the study was made with the thought in mind that it might serve as a method of determining the effect of the initial treatment, which was expected to cure the lesion and might suggest a technic that would reduce to a minimum the number of refractory cases. The lesion was single in fifty-four cases and multiple in thirty-seven; the frequency of occurrence was equal in the two feet. In eleven instances the warts occurred

on both feet. Fifty-eight patients obtained complete cure, whereas eighteen received no benefit. Cure, following subsequent treatment elsewhere, was reported by six patients; six others obtained merely relief of pain, and only partial or temporary relief was obtained in three instances. In forty of the fifty-eight cured patients the lesion or lesions disappeared after one treatment. Eleven patients required two treatments, five required three and two were cured only after four treatments. The average interval between the beginning of treatment and the disappearance of the lesions was six weeks. In thirty-two of the cured cases, removal of the wart was accomplished with a total of two and one-half skin erythema doses (one such dose equals 400 roentgens in air) of unfiltered radiation generated at 80 kilovolts, five patients received three skin erythema doses and seven only two doses, seven others received from two-thirds to three doses in one to three treatments over a period of time, and seven were given from one half to two doses of filtered radiation with 2 mm. of aluminum filtration at 100 kilovolts in addition to from one to two doses of unfiltered radiation. Of the eighteen patients who did not benefit from the treatment, eleven patients received two and one-half, one three, four from two-thirds to three skin erythema doses and two received both filtered and unfiltered radiation. Recently the authors have employed a technic using 100 kilovolts, 0.5 mm. of aluminum filtration at a distance of 40 cm., applying three doses. Early observations indicate that this technic may offer better curative results than other technics.

Comparison of Tests for Syphilis.—Breazeale and his associates compared the reliability of the Eagle, Ide, Kahn, Kline and Laughlen tests for syphilis: The agreement between the tests varied from 98.5 to 99.5 per cent. With 1,000 serums, all tests agreed with the exception of seventeen (98.3 per cent). In four instances, one test gave a doubtful reaction (+) when the other tests were negative; in the remaining cases at least two or more of the tests employed agreed. In the exceptions the variation was in weakly positive serums. In no instance was the Kahn reaction strong enough to be considered diagnostic (2 plus). Among the positive serums there was no instance in which there was any lack of agreement in the results obtained by the various technics. In 107 serums the results which the authors obtained agreed with the Wassermann tests obtained in three other laboratories in all but six cases. These were serums which had given negative or weakly positive Wassermann reactions. From the results which they obtained they feel that, when proper attention is given to the performance of the test, the different methods are equally reliable. Judging from their experience they believe that lack of agreement is probable only in serums which gave doubtful (+) or weakly positive reactions. The percentage of these is approximately the same for all tests. The choice of a test should be governed by the equipment available.

Glycerin Treatment of Elephantiasis.—Bowesman gave intra-arterial injections of from 2 to 3 cc. of sterile 10 per cent glycerin at intervals of one week to sixteen patients with elephantiasis and intravenous injections to four patients. The treatment alleviated to some extent the elephantiasis of the leg due to filaria. The intra-arterial injections are made into the femoral artery. Intravenous injections produce a less definite effect. The dull aching discomfort is lessened. Patients seen five months after cessation of the treatment showed limbs which either had the same size as at the end of treatment or remained smaller than before the commencement of treatment. Patients affected for two years or less appeared to improve until the measurements of the limb became equal. Patients suffering from the disease between two and four years were relieved of the chronic dull aching discomfort and showed a diminution of the measurements of the limb. These measurements never became normal, i. e. equal to the unaffected limb. All patients were improved to some extent, and there were no complications.

Periodicity in Neoplastic Diseases.—Webster traced the recurrence of 450 cases of neoplasm. The series includes carcinoma, sarcoma, recurrent papillomas, leukemia and lymphadenoma (with possibly Mikulicz's disease and other benign neoplasms). Periodicity has been clearly present in 96 per cent of the cases analyzed: usually it has been seen in a period of eight lunar months (thirty-three weeks); often in four lunar months (sixteen and a half weeks). The periodicity has been recognized most easily in superficial recurrences or in those readily accessible to clinical examination or to demonstration by x-rays. Neither surgical treatment nor irradiation has appeared to have an influence on periodicity. This has been shown by patients for whom a peak of rapid growth had been determined before the treatment began: recurrences followed at periods or half periods irrespective of the treatment. The alternatives appear to be cure or periodicity. For a high degree of statistical accuracy a series of patients with recurrent tendency should be examined at weekly intervals before and during probable recurrent maximums. The most conclusive proof of periodicity would appear to be success in prediction of recurrences, and already several successful predictions have been made. Full periods have been seen more than twice as often

as half periods in cases of carcinoma and leukemia. In eighteen patients with multiple primaries the signs of onset of the primaries (and any recurrences) have all fallen within one periodic scheme, as though each patient had had one disease with differing site manifestations. Neoplastic periodicity seems to bring forward circumstantial evidence in favor of the virus theory of cancer, as discussed by Gye and referred to by Webster. A virus origin is probable for human leukemia and lymphadenoma (proved for some skin papillomas, fowl leukemia and fowl sarcoma) and no other cause for the periodicity but a virus presents itself. Analysis of the dates of recurrence has shown that in breast cancer, sarcoma, leukemia and Hodgkin's disease almost half as many again recurrences have been seen in the first four months of the year as in each of the two other four month groups. This finding confirms the observations of Peacock and of Fraenkel on seasonal periodicity in animal tumors. The half periods may indicate a double infection, as in a double tertian malaria infection. (Half periods have been seen most commonly in sarcoma and Hodgkin's disease.) The signs in several patients have suggested a double infection. On a virus theory, either a chemical change or a stimulus occurs, or a vital reproduction occurs, at the half period instead of at the full term or its multiple, owing either to inherent seasonal or other accentuation of growth or to the patient's loss of resistance. Important practical applications of neoplastic periodicity are suggested in the fields of prevention, diagnosis, prognosis and treatment.

Clostridium Welchii Infection Following Abortion.—Dawbarn and Williams cite three fatal cases of infection with *Clostridium welchii* following abortion. In two of these the infection was a fulminating one in which the main feature was the occurrence of hemolysis, and a correct diagnosis was not made before death. The third case was one of a rapidly fatal infection of the uterus. In the two cases of septicemia the onset was so sudden and the manifestations were so dramatic that chemical poisoning was suspected. These suspicions were strengthened by the fact that both patients had been taking large doses of pills, presumably with the object of procuring abortion. The third patient also had a fulminating infection, although the clinical picture was different and the diagnosis was made soon after admission to the hospital. After death *Clostridium welchii* was found in various tissues in cultures, smear and films. In none of the three patients was the mode of infection determined. In every instance the pregnancy was an unwanted one, and all patients admitted having taken drugs with the object of procuring abortion, so that it seems probable that instrumental intervention had also been attempted.

Can We "Breed Out" Cancer in the Human Race? Madge Thurlow Macklin.—p. 587.

Neuropsychiatric Aspects of Bromide Intoxication.—Tod and Stalker aver that not only do physicians abuse bromides but that bromides are a common constituent of the "patent medicines" at which the neurotic, the sleepless, the depressed and many other unstable people snatch so readily. Many patients on admission to the Royal Edinburgh Hospital for mental disorders are in a toxic physical state and may show mental symptoms of a toxic kind in addition to those of the original disease; the

blood contains bromide and the toxic symptoms disappear when the drug is withheld. During the last four years at least ten patients have been admitted suffering from a frank bromide psychosis; two of these died from bromide intoxication. The clinical symptoms and signs are numerous and may appear in any order, in any combination and in any intensity. It not infrequently happens that when a patient is receiving bromide her anxiety, depression, agitation, excitement and the like become worse; occasionally the drug produces depression. The body is unable to distinguish between bromides and chlorides; consequently ingested bromide is found in the body wherever chloride is found. Consequently a diet poor in salt favors the retention of bromide in the organism. Prescribing bromide without knowing the chloride intake or the bromide saturation is the same as letting the patient take as much or as little bromide as he pleases. Any condition which might in any way impair the halogen excretion by the kidney predisposes to intoxication, e. g. all forms of dehydration, nephritis, arteriosclerosis, hypertension and pneumonia in which the halogen excretion almost completely stops. Persons who are weak, infirm or bedridden or who take little exercise are also predisposed. Any impairment of the function of the kidney predisposes to intoxication. Bromide intoxication may in itself impair the function of the kidney and so set up a vicious circle. The clinical features of bromide intoxication are essentially those of an organic reaction type (acute or chronic, mild or severe); that is, impairment of comprehension, interference with the elaboration of impressions, defects in orientation and retention, difficulty in activation of memories, marked fluctuation in the level of attention and emotional instability. There may be any gradation from a mild or chronic process to an acute delirium and the typical neurologic signs may also be present in any degree. Bromide intoxication may simulate any form of organic reaction; but whether the mental disorder is organic or functional a careful history in which the symptoms that led to the taking of bromide are differentiated from those which followed its use, the blood bromide estimation, the effect of withdrawing the drug and in some cases the neurologic signs should assist in making the diagnosis. The rate at which the symptoms clear up depends on the degree of intoxication, the integrity of the kidneys and the efficacy of treatment. The aims of treatment are to displace the bromide from the body and to sustain the patient's strength during the period of intoxication. The administration of sodium chloride in large amounts causes a rise in the amount of halogen and consequently of bromide excreted. Salt is best given in capsules in doses of 4 Gm. three times a day. The intestine and bladder should be attended to; constipation is frequent and retention of urine occasionally occurs. A patient in delirium requires the most careful nursing, and when possible he should be in the quiet of a single room with a special nurse. Most sedatives are dangerous in such cases as they increase the toxemia, but, if the patient is sleepless, paraldehyde should be given at night.

Mottled Teeth Endemic in Travancore.—Pillai observed that a section of the people (about 100 families) residing at one end of the town of Nagercoil in South Travancore has mottled teeth. The enamel of the teeth of these people, particularly in

the case of the adults and the older members of the community, would appear to have been subjected to a sort of corrosion followed by pigmentation. In addition to the pigmented condition and the consequent disfigured appearance, the mottled teeth have also been found to be defective in structure and strength. The analysis of the drinking water supply of the affected persons shows the presence of from 0.4 to 0.5 part per hundred thousand of fluorine, whereas the water supplies for the other sections of people contain practically no fluorides. In other respects the composition of the incriminated water is similar to that from adjoining areas.

Substitutes for Morphine.—Myers and Davidson studied the effect of dihydromorphinone hydrochloride (dilaudid), dihydrocodeinone (dicodid), hydrochloride of dihydroxycodeinone (eukodol), diacetylmorphine and morphine on the human alimentary tract in young healthy adult male medical students. Barium sulfate meal and x-ray methods were made use of for the observations. The effects of dilaudid closely resemble those of morphine. Dilaudid produces a condition of increased tone in the pyloric and ileocolic sphincters resulting in delayed emptying of the contents of the stomach into the duodenum and a delayed passage of the intestinal contents into the cecum. Dicodid has a much weaker action on the pyloric and ileocolic sphincters than either morphine, diacetylmorphine, dilaudid or eukodol. It causes only a negligible delay in the passage of food up to the time of three hours, it being normal at six hours owing to a hastening of the motility rate. Eukodol has an action resembling that of morphine. All these drugs possess well marked analgesic properties. No gross rectal symptoms were observed in any of the subjects under observation.

Muscle Action in Repair of Joint Tissues.—Smart declares that in order to maintain a tissue in a healthy state the regular normal fulfilment of the function of the arterial, venous and lymphatic circulations is essential. He shows the great part played by muscular contraction and relaxation in promoting these circulations and in aiding the removal of fluids infiltrated into the tissues. Movement—that is muscular action—therefore plays a special part in the efficiency of the circulatory system generally, and conversely when muscles are

hypotonic and wasted, the physical and chemical phenomena coincident with their normal activity, which is so essential to their efficiency and sensation of well being, are seriously interfered with, and this has a detrimental effect on the nutrition not only of the muscles but of all the neighboring tissues as well. It is possible by the application of a properly designed electrical unit to utilize muscular activity in the treatment of inflamed and painful joints. The correct application of the right type of electric current reproduces painless alternate contractions and relaxations of the muscles and, provided the rate and degree of the contractions and the relaxations are under perfect control, there is no more potent means of stimulating rapid and complete absorption of fluids from the tissues. Controlled stimulation of muscles to produce alternate contractions and relaxations restores the tone to the muscles, prevents intermuscular and intramuscular adhesions by keeping the tendons and other parts moving, and increases the blood and lymph supply and the onward movement of tissue fluids, thus stimulating the rate of repair by encouraging the rapid absorption of waste products. The method is used solely to encourage the restoration of normal function by artificial stimulation, with all the attendant beneficial changes resulting from muscular action, only during the period that normal muscular function is lost or diminished. Muscular stimulation rapidly restores the tone and redevelops wasted muscular atonicity, which, if reached, no amount of voluntary exercise, even when combined with skilled and prolonged massage, will produce complete redevelopment, whereas the response to artificial electrical stimulation is striking and, provided the path of the nerve is intact, ends in certain and rapid recovery and even overdevelopment if pushed too far.

Phosphorus Poisoning in Match Making.—Oliver states that, since Sevéne and Cahen of France recommended the substitution of phosphorus sesquisulfide for white phosphorus, a safe and equally useful substitute had been found for the manufacture of the "strike anywhere" match. Never since in Great Britain has there been recorded a case of suicidal or accidental phosphorus poisoning or any new cases of phosphorus necrosis or illness among the workers. At an international convention in Berne in 1906 many of the civilized nations supported this line of action and a few years ago China and Japan also joined the convention, so that under present conditions it is hardly likely that one shall ever again hear of phosphorus poisoning, and certainly never of industrial phosphorus necrosis.

Faulty Detoxication in Schizophrenia.—Quastel and Wales propose to demonstrate that catatonic patients as a class show a definite disability to detoxicate benzoic acid at a normal rate and imply that in this subgroup of schizophrenic patients there is present an abnormality which is concomitant with the development of the psychosis and may be partly responsible for it. Sixty-seven patients were chosen who on thorough examination showed no evidence of hepatic or renal disorder. Of the sixty-seven patients, forty-five were schizophrenic and eighteen of these were classified as catatonic. Twenty-three of twenty-seven noncatatonic patients in the schizophrenic group gave

hippuric acid excretions of the normal value and normal range of variation. Of the eighteen catatonic patients, all without exception gave values lower than the average normal. A number of these patients were examined on more than one occasion at intervals of several weeks. The average value of benzoic acid excreted in the schizophrenic noncatatonic group was 3.4 Gm. and the average deviation from the mean was ± 0.4 Gm. The average value of benzoic acid excreted in the catatonic group was 2.2 Gm. and the average deviation from the mean was ± 0.5 Gm. Among the twenty-two nonschizophrenic patients (of whom twelve fall into the manic-depressive group) several gave diminished outputs of benzoic acid. The results suggest that a metabolic disturbance is present, probably in the liver. The phenomenon appears to present a metabolic abnormality existing in catatonic patients. None of the catatonic patients studied had had chemotherapy for several weeks, so that the results cannot be complicated by this factor. The results are unlikely to be due to a deficiency of amino acid. The fact that all the catatonic patients showed a diminished ability to excrete hippuric acid after benzoate administration makes it unlikely that the phenomenon is purely fortuitous. The phenomenon may also find an explanation in delayed absorption of benzoate or of aminoacetic acid from the intestine. Experiments to determine this are now in progress. The long duration of illness of the catatonic patients may be related in some manner to the impairment of benzoate detoxication.

Poliomyelitis in Victoria and Tasmania.—Burnet and Keogh isolated a typical poliomyelitis virus from spinal cords of several patients who had died during the 1937 Victorian and Tasmanian epidemics of poliomyelitis. All the monkeys that were inoculated from the cords had typical symptoms, with some variability in the incubation period. The shorter the incubation period, the more severe were the symptoms. On the whole, the virus appears to be more readily transferred to the monkey than strains obtained in nonepidemic periods. The variability in intensity of symptoms was also evident in sub-inoculations. Monkeys recovered after infection with the virus are still partially susceptible to infection by the Rockefeller Institute MV strain.

*Histamine Therapy in Rheumatic Pains. D. Vincart-Van Geem.—p. 1345.

Histamine Therapy in Rheumatic Pains.—Vincart-Van Geem, after reviewing the previous history of histamine therapy in the form of ionization or dielectrolysis, discusses the chemistry and the mode of action of histamine. Then he points out that investigations by Deutsch revealed that muscles normally require a certain quantity of histamine, which they liberate spontaneously in the course of movement and exercise. If the muscles are more or less immobilized by a pathologic condition like that of rheumatism, the resulting deficiency in histamine intensifies the pathologic state and produces contracture with all its consequences: pain, articular ankylosis, muscular contracture, capillary disturbances and so on. For this reason it was decided to introduce histamine. Discussing its mode of administration, the author says that ionization and intradermic injection are the methods of choice. Ionization with histamine was first employed by Ebbecke in 1922 and Deutsch adapted this method. The author himself slightly changed the technic employed by Deutsch. He uses several thicknesses of gauze, which are saturated with a solution of histamine dihydrochloride (10 mg. per liter of distilled water) and which are covered with a metallic foil. This electrode is applied to the skin and it is connected with the positive pole of a source of galvanic current. The other electrode, which is saturated with water, is connected with the negative pole and during the treatment it is held in the patient's hand. The intensity of the current varies between 3 and 10 milliamperes; the time of application is inversely proportional to the current strength. The author found that three minutes with 5 milliamperes was the most convenient form of application for the majority of patients. The intradermic injection of histamine employs ampules of 1 cc., containing 0.5 mg. of histamine dihydrochloride in an isotonic solution, the pH of which is around 7. One or two drops of the solution is deposited into the skin at distances of 1 or 2 cm. From fifty to seventy-five can be made with one ampule. In one group of patients the ionization treatment and the intradermic application were given on alternate days, but the ionization treatment was preferred by most of the patients. Regarding the indications for the histamine therapy, the author says that he considers it advisable in all acute and chronic myalgias, in arthralgias due to acute and chronic periarthritis, in the sequels of infectious rheumatism, in traumatism such as fractures and sprains, in essential or secondary neuralgias, in rheumatism and in cellulitis. However, the treatment is contraindicated during the evolutive period of acute infectious rheumatism.

Pegging in Diaphysal Fractures. H. Lafitte.—p. 177.

Retroglenoid Abutments in Posterior Dislocations.—

Fèvre and Mialaret stress the advantages of applying in relapsing posterior dislocations of the shoulder the excellent procedure of abutment, which is so frequently employed in the anterior dislocations. They say that this method is not entirely new, it having been employed with good success by Rocher and others. But although Rocher had given a detailed description of the technic, the procedure seemingly has not entered current practice. The posterior dislocations justifying this intervention are rare; in adults only 3 per cent of the relapsing dislocations are retroglenoid. In children, however, these dislocations seem to be more frequent, but the abutment has as yet not received the attention it deserves in the treatment of congenital dislocations of the shoulder. The authors report their own experiences with this treatment in a child aged 11.

The functional results obtained in this case were perfect. Following a detailed description of this case the authors discuss the indications for this intervention and then give a detailed description of the technic. They first describe the withdrawal of the grafts from the tibia and, in discussing the intervention on the shoulder, they say that in simple cases the retroglenoid abutment can be executed by a subdeltoid posterior incision. In the difficult cases (difficulty of reduction, of maintenance of head of humerus) the intervention is more extensive; the classic method of Duplay-Kocher is used or it is modified and simplified for children.

46: 1225-1232 (Aug. 10) 1938

*Painful Syndromes of Extensive Invasion of Skeleton in Patients with Cancer of Breast. J. Ducuing.—p. 1225.

Skeletal Syndromes in Cancer of Breast.—According to Ducuing, cancer of the breast gives rise to osseous metastases more frequently than was formerly believed. These metastases may be circumscribed and isolated or diffuse and extensive. Although a secondary isolated nucleus can be extremely painful, the author gives his attention chiefly to the study of the pain in the course of the extensive invasion of the skeleton. The cancerous invasion of the bones is not always painful; it may evolve insidiously to the cachectic state or until it becomes manifest either by a spontaneous fracture or by an osseous thickening. The conditions described here are essentially the painful manifestations of isolated osseous involvement; the patient suffers "in the bone," but these pains precede quite frequently the signs of medullary radicular and truncal invasions or compression, which constitute the syndromes described by neurologists. But the lesions which cause the osseous pains do not always terminate in those that provoke the nervous syndromes; in some cases they remain localized in the skeleton. After citing the various mechanisms of osseous invasion (by way of the blood and the lymphatics), the author says that anatomoroentgenologic studies reveal that there are three principal types of extensive invasion of the bones by mammary cancer. In his opinion, every extensive invasion into the osseous system begins with vertebral involvement; then the lesions spread to the shoulder girdle and then to the pelvic girdle, and finally they may involve the entire skeletal system. Studies on the roentgenograms confirm the anatomopathologic observations and show that there exist three forms of cancerous skeletal lesions: (1) the osteoclastic or osteoporotic form, (2) the osteoplastic or osteoconstructive form and (3) the mixed-form. The conditions under which the painful symptoms make their appearance differ. The cancer of the breast may or may not have been treated. The general condition of the patient may be florid or cachectic. The florid condition is surprisingly frequent in these patients. The onset of the painful syndrome may be insidious, under the form of slight, fleeting attacks; it may be abrupt, in the form of "rheumatismal" crises, or it may be sudden and persistent. The character of the painful syndromes varies with the localization of the cancerous metastases. The patients complain of pains in the back, in the shoulders or in the hips. The author gives detailed descriptions of these syndromes and in the conclusion he points out that these painful syndromes develop more frequently than formerly. He thinks that this might be due to the fact that the present day treatment of mammary cancer augments the rate of survival for these patients. On the other hand, it may only have the appearance of an increased frequency, because more cases are recognized now than formerly.

Teniasis as Cause of Uncontrollable Hyperemesis Gravidarum. R. Oehlke.—p. 153.

Experiences in Care for Premature Birth. H. Volz.—p. 158.

Mongolism.—Kehrer describes four cases of mongolism in newborn infants and one of the extremely rare cases of familial mongolism. The manifestations of the developmental disturbances in the brain are already so pronounced in the newborn

infants that a diagnosis is possible without difficulty. In addition to the more or less characteristic facial expression, the following symptoms are of diagnostic significance: general muscular hypotonia, cutis laxa which is present chiefly on the occiput and on the back of the neck, immobility, somnolence and apathy, and the shortness and inward curvature of the terminal phalanges of the fifth fingers (Siegert's sign). The diencephalic-adenohypophyseal system may be involved in the developmental anomaly of the brain. This results in endocrinopathies, which may exist at birth but which do not become manifest until later. The observation of some authors that mongoloid children are usually borne by mothers who have passed the age of 40 was corroborated in only one of the four newborn. The author thinks that mongolism is caused partly by impairment of the germ plasma (ovum or spermatozoon), partly by damage to the embryo. In one of the four cases the mother had passed through an epidemic encephalitis two years before the birth of the child. In another case, consanguinity in the distant ancestry may have played a part.

*Treatment of Morbus Maculosus Werlhofii. E. Jacobson.—p. 991.

Treatment of Morbus Maculosus Werlhofii.—Jacobson says that essential thrombopenia, which is better known under Werlhof's term "morbus maculosus," still presents a therapeutic problem. Most of the treatments that have been employed, such as blood transfusion, roentgenotherapy, protein therapy, various styptic preparations and vasoconstrictive remedies, are merely temporary, palliative measures. In the severe cases splenectomy is employed. As one of the reasons why there is as yet no satisfactory treatment, the author regards the fact that the cause of morbus maculosus werlhofii is not known. After citing some of the theories that have been advanced with regard to the cause, he points out that thrombopenia is one of the chief symptoms but that an important role has been ascribed also to the behavior of the vessels, particularly the capillaries. He resorted to treatment with phenylhydrazine for the first time in 1931. The favorable results obtained in the first cases induced further trials with this treatment. In all, it was employed in twenty-eight cases. The expectation that the phenylhydrazine would increase the number of thrombocytes was not realized, but in spite of this it produced improvement and thus fulfilled the purpose of the medication. In this connection it is pointed out that even after splenectomy the number of thrombocytes remains quite low. In some cases in which there was at first no therapeutic response to the phenylhydrazine the treatment was repeated several weeks later. Lack of tolerance or undesirable secondary effects were never observed. Phenylhydrazine hydrochloride was given during meals in doses of 0.1 cc. (enclosed in gelatin capsules). The total dose varied between 0.7 and 1.5 cc. Discussing the results of the treatment, the author says that in nineteen of the patients, the hemorrhagic tendency disappeared. This cure has so far persisted for from three to seven years. The other nine patients could not be traced.

*Fourth Derivation in Electrocardiography. F. De Matteis.—p. 86.

Nephropathy in Course of Brill's Disease. S. Dini.—p. 92.

Hemolytic Jaundice with Increased Globular Resistance. F. Rietti.—p. 95.

Fourth Electrocardiographic Lead.—De Matteis describes the fourth derivation as that obtained by placing a "different" electrode at the left frontal wall of the thorax and an "indifferent" one at either the posterior wall of the thorax (opposite to the "different" electrode) or at the left arm or leg. He obtained electrocardiograms in the fourth derivation by placing the "different" electrode on the left parasternal region and the indifferent electrode at the left arm. He observed the behavior

of the fourth derivation in 700 electrocardiograms of 207 persons. The group included normal persons and patients who were suffering from either adenoids or diseases of the heart. He found that the electrocardiogram which is taken in the fourth derivation in normal persons is normal in all cases. The pathologic changes of the fourth derivation electrocardiogram show involvement of the ventricular myocardium and of the coronary system in some cases of angina pectoris in which the electrocardiograms which are taken by the peripheral derivations are normal. Alterations of the fourth derivation in association with those of the peripheral derivations are of value in confirming the clinical diagnosis of myocardial infarct and determining the seat of the infarct. A pathologic fourth derivation does not show, specifically, myocardial infarct from coronary thrombosis. It may appear in compensated or decompensated insufficiency of the mitral valve, aortitis, total arrhythmia, myocarditis with generalized arteriosclerosis, acute rheumatic myocarditis, exophthalmic goiter and poisoning from digitalis. It shows functions of certain zones of the ventricular myocardium and of the coronary system which are not registered by the peripheral derivations.

*Nonspecific Protein Treatment in Inflammation of Female Internal Genitalia. G. Amabile.—p. 199.

Reticulocytosis and Tuberculosis in Obstetrics and Gynecology. G. Bezzi.—p. 209.

Protein in Inflammation of Female Genitalia.—Amabile administered injections of 5 cc. of boiled cow's milk to fourteen patients who had inflammations of the internal genitalia. Determinations of the leukocytes and of the leukocytic formula were made before and twenty-four and forty-eight hours after administration of the injection. The author found that the injection is followed by increase of the temperature and of the number of leukocytes, and diminution of the neutrophilic leukocytes and increase of the lymphocytes. The reaction lasts from twenty-four to forty-eight hours. Lymphocytosis permanently increases as the patient improves. According to the author, heterologous protein therapy stimulates a special reaction of the lymphocytes and improves the circulation of the lymph with consequent transportation of antibodies to the inflamed tissues. Increase of the lymphocytes after heterologous protein therapy shows a reaction of the body which induces favorable changes in the clinical evolution of the local inflammation, especially in puerperal infection. In the course of the latter, the sooner the administration of the treatment the better the results. The treatment is easily administered, is harmless and is well tolerated by the patients.

Chronic Urticaria: Case. A. A. Fernandez and A. B. Storace.—p. 576.

Generalized Osteochondrosis.—Gamboa and Salvati studied a form of dystrophy of the bones, the so-called Morquio's disease, which was described for the first time by Morquio in the *Archives de médecine des enfants* 32:129 (March) 1929 and abstracted in THE JOURNAL May 4, 1929, page 1560. Since then thirty-five cases have been reported in the literature. The disease has some similarity to osteochondritis, but it is not of an inflammatory origin. It is familial and sometimes hereditary. Generally the patients are children who develop normally until they begin to walk. At this time, and in the course of a few months, all the bones and large joints become permanently deformed. There is no pain during the process of deformation. The patient's head projects forward because of the presence of dorsal kyphosis. The root of the nose is slightly sunk and the eyes appear to be farther apart. The thorax clavicles are raised to the point of hiding the neck. The thorax becomes short and enlarged (barrel shaped) with the sternum

projected forward. The hip joint is in flexion and there is knock knee and flatfoot. The movements of the joints are either exaggerated or restricted. The muscles lack strength and the patients have the waddle of a duck. Roentgen examination shows processes of rarefaction deformation or destruction of the bones. The craniofacial diameters are slightly diminished and the sella turcica is greater than normal. The amount of calcium and phosphorus in the blood is either normal or increased. In the majority of cases the mentality is normal and the Wassermann reaction is negative. As age advances the anatomic lesions of the bone improve but the deformities are irreversible. Either consanguinity or endocrine disturbances have been considered the pathogenic factors of the disease. Syphilis, alcoholism and toxic infections seem to play no pathogenic role. The disease can be easily differentiated from other forms of bone diseases. Up to now endocrine treatment has failed. The actual aim is to prevent further deformities by an early diagnosis and care of the patient all through the process of ossification. At this time the progress of the disease stops. Orthopedics seems to be advisable in correcting deformities, but up to the present time it has not been resorted to. The author reports a case, the thirty-sixth in the literature.

Body Heat and Surgical Intervention.—It is pointed out by von Brandis that the undisturbed process of the vital functions of the human or animal organisms depends on a definite temperature. In this extensive report he describes his investigations on the body temperature before, during and after surgical interventions. He made these studies in order to gain insight into the thermoregulation of persons receiving surgical treatment. In view of the close connection between all functions under vegetative regulation, it was to be expected that under the influence of the surgical treatment the heat economy of the body would undergo changes similar to those that are known to occur in the circulation and the metabolism. Summarizing his observations, the author states that in surgical interventions which are made under general anesthesia the regulation of the body temperature is greatly impaired; in those made under spinal anesthesia it is partly subdued and in those under local anesthesia it is not impaired and may even be stimulated. Under general and spinal anesthesia, these changes become manifest in a noticeable subsidence in the heat formation, that is, in a cooling of the nuclear temperature, as well as in disturbances in the giving off of heat, in that it is increased in the peripheral regions of the skin. In interventions under local anesthesia the stimulation of the thermoregulation becomes manifest in a mild increase in the nuclear temperature, whereas the giving off of heat is not changed. The author emphasizes that under general and spinal anesthetics the thermoregulation is only subdued, not completely excluded. He observed that even under deep narcosis the regulation of the discharge of heat will become operative again at the moment when this becomes necessary in the interest of the organism on the whole. The author regards as especially important the observation that the aforementioned methods of anesthesia act differently on the heat regulation only so far as they are means to induce general, spinal or local anesthesia. The numerous substances that are available to produce any of these three types of anesthesia differ among themselves in their action on the thermoregulation only in degree. The author thinks that here the different toxicities are decisive. In the same way the impairment of the thermoregulation differs according to the condition of the patient; that is, his resistance to the operation and the type and location of the disorder as well as the extent of the intervention. The

parallelism in the behavior of circulation, metabolism and thermoregulation, that is, of the functions that are under vegetative regulation, is so complete that the effects of surgery and anesthesia appear at the same time and in the same form in all of them. The thermoregulation with its extraordinary constancy suggests that it might have a predominating position over some of the other functions that are under vegetative regulation. The author concludes that the continuous observation of the entire economy of body heat, that is, of the production as well as the discharge of heat, gives such reliable information about the vital functions before, during and after surgical interventions that the results are not only of scientific interest but also of clinical value.

Treatment of Trigeminal Neuralgia.—Von Brücke says that at the surgical clinics in Vienna and Graz trigeminal neuralgia is treated by means of the injection of alcohol into the gasserian ganglion. The injections are made under roentgenologic control, that is, the foramen ovale is demonstrated by means of roentgenography. The foramen ovale can be roentgenologically demonstrated without difficulty on axial exposures of the cranial base, but such exposures are of no practical value for reaching the gasserian ganglion by means of the puncture needle. It was found that the direction of the rays had to be identical with the direction of the needle. This direction has been designated by Härtel as the trigeminal axis; it passes from the trigeminal impression on the anterior surface of the pyramid in the direction of the third branch and through the center of the foramen ovale. Since the success of aimed roentgenograms depends largely on an exact adjustment of the x-ray tube, von Brücke devised an aiming apparatus. He describes this aiming apparatus, which is used not only for the adjustment of the x-ray tube but for the introduction of the needle into the foramen ovale. After the needle has reached the foramen the position is again controlled by roentgenoscopy. The injection is made with 90 per cent alcohol, which is given in small successive amounts of 0.2 cc. each. The total amount injected in one session varies between 0.6 and 1.5 cc.; more than 2.5 cc. should never be injected at one session. The author says that alcohol injection of the gasserian ganglion should be resorted to only in severe cases of true idiopathic trigeminal neuralgia and not until the usual conservative methods, including alcohol injections into the peripheral nerves, have been exhausted. He evaluates the results that have been obtained in twenty-five cases. He concludes that the alcohol injection into the gasserian ganglion under roentgenologic control is a reliable method which, because it is not dangerous, should be retained in spite of the improvements in the surgical interventions for trigeminal neuralgia.

*Bitterlings for Testing Male and Female Sex Hormones. E. Glaser and F. Ranftl.—p. 1120.

Bitterlings for Testing Sex Hormones.—Glaser and Ranftl criticize studies recently reported by Duyvené de Wit and emphasize that the growth of the ovipositor of female bitterlings belongs to those secondary sex characters which can be influenced by female as well as by male hormones; the female hormone merely has a somewhat more pronounced effect on the growth of the ovipositor. Otherwise it may be assumed that here, as in the Allen-Doisy test, the sex hormones of various structures (estrone, beta-estradiol, estriol, equilin, equilenin and so on) will show quantitative variations, which can be observed also during the different seasons. If these peculiarities of the ovipositor test on bitterlings are taken into consideration, the test can be used, although not alone, at least as a corroborating test in addition to other tests, for certain clinical purposes. The authors think that contradictory reports in the literature find their explanation in the fact that the investigators put

especial stress on one or on another property. Regarding the "wedding dress" of the male bitterling, the authors maintain that it is the best test for the male hormone. It is not only cheap and simple but it has a degree of sensitivity that is reached by no other biologic test for the male sex hormone. The physiologic actions of progesterone correspond to a large extent to those of the so-called pure male sex hormones. Thus progesterone produces the "wedding dress" in male bitterlings, but it also increases the growth of the ovipositor in female bitterlings. If administered to mice during the phase of proliferation, progesterone prolongs the cycle; if administered during the secretory phase, it hastens the onset of estrus. The combined administration of male and female hormones shows additive effects in the ovipositor test on female bitterlings, but in the "wedding dress" of the male bitterling the antagonistic action of male and female hormones becomes evident; if sufficiently large quantities of female hormones are added, the male hormone remains ineffective.

*Apoplectiform Onset of Disorder in Case of Cerebral Tumors. A. Stender.—p. 123.

Acute Multiple Sclerosis.—According to Kreissel, the differentiation of acute multiple sclerosis from disseminated encephalomyelitis still awaits clarification. Whereas some classify acute multiple sclerosis and even multiple sclerosis with disseminated encephalomyelitis, others maintain that acute multiple sclerosis is a typical multiple sclerosis with an especially acute course. The author thinks that, as long as the etiology is not yet completely explained, a differentiation can be based only on clinical and anatomic aspects. He describes anatomic studies on the brain and the upper portion of the cervical spinal cord of a patient who died following acute multiple sclerosis. He emphasizes the changes that are identical with those of multiple sclerosis, particularly as regards their localization. He gives a detailed description of a peculiar, border-like process on the periphery of the cerebral peduncles, of the pons and of the medulla oblongata and compares this process with similar ones that have been described in the literature. He was able to detect some similarities with the encephalitis that develops after measles or after vaccination. Nevertheless, he shows that disseminated encephalomyelitis can be differentiated from the encephalomyelitis that develop after measles and vaccination as well as from acute multiple sclerosis. In the histopathologic picture of disseminated encephalomyelitis, the inflammatory infiltrative process predominates; however, in that of the encephalomyelitis after measles and vaccination, the inflammatory infiltrative reactions are much less severe than the proliferations of the glia. The described case is characterized by the acute disintegration of the medullary sheaths; this is much more noticeable than the inflammatory reaction on the vessels. In view of the disintegration of the medullary sheaths and of the localization of the processes, the diagnosis of acute multiple sclerosis was regarded as justified. The clinical aspects of the case were like those of multiple sclerosis.

Apoplectiform Onset in Cerebral Tumors.—Stender reports twelve cases of cerebral tumor which began with an apoplectiform attack and subsequent hemiplegia. In the majority of the cases the apoplexy appeared suddenly, but in some cases unsuspected prodromal symptoms preceded it. The clinical picture immediately after the apoplectiform attack was usually that of an extensive or even of a complete exclusion of the corticospinal tracts of the involved hemisphere; that is, there was hemiplegia and hemianesthesia and in several instances there existed in addition a hemianopia and an aphasia. Objective signs of cerebral pressure, particularly choked disk, were lacking in the majority of cases, but in several patients the pupillary reactions were disordered. With one exception, all of the cases terminated in death and the majority of patients survived only a comparatively short time after the apoplectiform attack. Thus

the prognosis is unfavorable in the cases of cerebral tumor which begin with an apoplectiform attack. After citing the localization of the tumors and the histologic aspects, the author discusses the pathogenesis. He regards hemorrhages from a ruptured vessel of the tumor or malacia by vascular occlusion from the pressure of the tumor as possible causes of the apoplectiform attack. However, postmortem observations indicated that in the majority of cases an acute cerebral edema was the direct cause of the apoplectiform attack.

*Segmental Osteotomy. A. S. Pertsovskiy.—p. 307.

Multiple Segmental Osteotomy.—According to Pertsovskiy the various methods of osteotomy thus far proposed failed to solve the problem of actual elongation of the limb. The inadequacy of the methods is even more evident when in addition to the lengthening of the extremity it becomes advisable to correct its position. The multiple osteotomy method of Bogoraz is capable of accomplishing both results. It is applicable in cases of angular ankylosis as well as in cases of ankylosis of the femur in the hip joint with the extremity in extension. In addition the method is capable of accomplishing actual lengthening of the limb without altering the relations in the hip joint. The author's roentgenograms demonstrate that, as the result of traction by a Kirschner wire through the diaphysis, the bone segments in this operation become separated from the upper fragment and the lower fragment of the femur as well as from one another by a distance of from 2 to 3 cm. and that they are maintained in proper alignment. The greatest elongation obtained by the author amounted to 9 cm.

Tuberculosis in Castrated and Noncastrated Animals.—According to van Bokkum, it has long been known that the chance of contracting tuberculosis differs in various periods of life. The period of puberty and the period of the height of the sex function (around the age of 30) are supposedly especially unfavorable. Animal experiments have been made to determine whether there are connections between the function of the sex glands and the tuberculous infection, but in many of these experiments the number of animals was rather limited, so that the author decided to employ a larger material to investigate the influence of castration on the susceptibility to tuberculosis. He made his studies on two series of animals. The first series consisted of five male and five female castrated guinea-pigs and of five male and five female guinea pigs that were not castrated; that is, in all, this series consisted of four groups of animals. The animals were inoculated with human tubercle bacilli the virulence of which had been tested previously on six guinea pigs. Five months had elapsed since the castration before the inoculations were made. In a second series of experiments the author again employed four groups of guinea pigs, but in this series the groups consisted of from seven to nine animals each and the inoculations with tubercle bacilli were made four months after castration. As regards neither the length of survival nor the anatomic dissemination of the tuberculous processes was it possible to detect differences in the various groups of animals. The author concludes from these observations that there is no reason to correlate the differences in the susceptibility for tuberculosis during the different periods of life to the gonadal function.

UROLOGIC CONDITIONS SIMULATING CHRONIC GLOMERULONEPHRITIS

CHAIRMAN'S ADDRESS

A. J. SCHOLL, M.D.

LOS ANGELES

Since certain curable diseases of the urinary tract may simulate chronic glomerulonephritis, it is essential that such curable diseases are not overlooked. That they are occasionally overlooked even in the most advanced medical centers is attested by the words of O. H. P. Pepper.¹ He said: "We have had patients die in our hospital with a diagnosis of chronic Bright's disease of some type or other, to be horrified at autopsy that the condition was altogether a lower urinary tract obstruction with hydronephrosis, an obstructive lesion destroying the glomeruli just as effectually as glomerulonephritis does, giving impaired renal function."

UREMIA

Uremia is the most prominent symptom of patients who have chronic glomerulonephritis and of those who have a lesion of the urinary tract of an obstructive or infectious nature. It is observed frequently as a complication of nephritis, and for this reason unless patients with uremia exhibit obvious signs of pathologic change in the urinary tract they are thought to have chronic glomerulonephritis.

Any disease or injury whereby so much of the renal tissue is destroyed that the remainder is unable to compensate for the loss may cause uremia. Renal insufficiency does not develop if a small amount of normal parenchyma is left. The work of Tuffier² thirty years ago and that of Bobroff³ later demonstrated that life could be maintained if a very small portion of a normal kidney remained. Tuffier, in his experimental work, performed total unilateral nephrectomy plus more or less extensive resection of the other kidney in an endeavor to find the exact quantity of normal renal tissue necessary for the maintenance of life. He found that there was a definite regeneration of tissue in the remaining segment only when the portion allowed to remain was sound.

A number of early writers attempted to distinguish between the uremia associated with nephritis and the

uremia common to anuria. Ascoli⁴ in 1903 made two divisions: (1) urinary poisoning, in which the symptoms of the disease are similar to those found in anuria produced by mechanical means and are caused by retained metabolites and (2) renal uremia, characterized by sudden convulsive seizures, which he believed were caused by certain unrecognized nephrolyses. According to Fishberg,⁵ Widál arrived at a similar division from the point of view of blood chemistry. He found that in the clinical picture corresponding to Ascoli's urinary poisoning the amount of urea in the blood is increased and he therefore called it azotemia, believing that the symptoms were due to uremic poisoning. The acute convulsive type he termed chlor-uremia, on the assumption that the retention of chlorides caused the convulsive seizures.

Volhard⁶ combined the two conditions. He said: "When we compare the symptoms which appear only with renal insufficiency and which we have designated as symptoms of true uremia with those occurring in anuria, we find them almost identical."

The urologist considering uremia thinks of the retention of nitrogen in the blood associated with obstruction of the vesical neck or of that associated with calculous anuria. He attempts to relieve the obstruction, to subdue the infection or to drain the offending accumulation, and he considers the prognosis as at least not unfavorable. The internist considering uremia frequently thinks in the unfavorable terms of chronic nephritis. The rapidly fatal outcome of the disease in patients who have a high value for retention of nitrogen is constantly before him. Chace and Myers⁷ reported a series of cases in which the patients who had chronic glomerulonephritis associated with a value for retention of creatinine of more than 5 mg. per hundred cubic centimeters of blood died early in the course of the disease. In contrast to these figures, patients with obstructive lesions whose concentration of urea was from 80 to 100 mg. per hundred cubic centimeters of blood and whose values for creatinine were from 8 to 10 mg. usually recovered after proper treatment.

Rowntree,⁸ in discussing uremia, stated that sometimes by clinical methods only it is impossible to recognize whether the uremia is due to organic or to functional changes. The development of uremia in a case of marked chronic nephritis offers little in a permanent way as a result of treatment; whereas in the

presence of an identical clinical picture encountered in a case in which the kidney has been injured by back pressure, the prognosis may be good. Wohl and Brust,⁹ reporting uremia with conditions other than chronic glomerulonephritis, stated that the impression gained from a perusal of the literature, as well as from modern textbooks of medicine, is that an increase in the presence of nitrogenous waste products in the blood is indicative of chronic glomerulonephritis. The importance of recognizing these states clinically and early lies in the fact that many of them mistakenly are thought to be of renal origin, especially since traces of albumin and some casts are frequently found on examination of patients whose disease is not primarily of renal origin.

Ascoli⁴ stated positively that the uremia which he called urinary poisoning was quite different from that associated with chronic glomerulonephritis. The patient, as noted by Foster,¹⁰ who studied three patients whose only functioning kidney was removed surgically because of some disease, has few or none of the symptoms which mark the conception of spontaneous uremia. Convulsive seizures are rarely observed, nervous phenomena are conspicuously lacking, headaches are rare and vomiting only occasionally occurs. Foster stated that urinary poisoning is produced by some rather sudden change in the excretory organs, resulting in prompt flooding of the tissues with nitrogenous waste products. When failure of elimination is not so rapid and the waste products accumulate in the tissue fluids more gradually, it is conceivable that the cells acquire a certain degree of tolerance and are not so injured as they appear to be when the change is sudden.

The following case, previously reported by Scholl and Foulds, is one of anuria which resulted from a long-standing complete obstruction of a single functioning kidney. Involving an excessively high value for retention of nitrogen, this case illustrates the freedom from uremic symptoms and the clarity of intellect common to patients who have anuria, contrasting sharply to the stupor, anorexia and convulsions of those who have chronic nephritis.

CASE 1.—A woman aged 60, who complained of frequency of micturition and of dysuria, for three months had had dull intermittent pain in the left side of the abdomen and occasionally hematuria.

When first seen she was voiding small amounts of urine every half hour and had lost 20 pounds (9 Kg.) during the previous four months. The blood pressure in millimeters of mercury was 176 systolic and 106 diastolic. Examination of the eyegrounds gave negative results. A single specimen of urine had a specific gravity of 1.002; the urine was acid in reaction and contained a small amount of albumin, a few erythrocytes and many pus cells. There was no return of phenolsulfonphthalein in two hours. The concentration of urea was 130 mg. and that of creatinine 3.3 mg. per hundred cubic centimeters of blood. Neither ureteral orifice was seen on cystoscopic examination, although there was a scar of inflammation in the region of the left opening.

For sixteen days the patient voided from 400 to 1,200 cc. of urine a day. For the next fourteen days the only urine secreted was .25 cc., which was voided in a single day. Moderate edema of the eyelids appeared. Her appetite was poor and she vomited occasionally. Several days after the onset of anuria a mass became evident in the region of the right kidney. The concentration of blood urea gradually rose until it was 527 mg.

per hundred cubic centimeters of blood and the concentration of creatinine increased to 26.6 mg., and still she remained clear mentally and had no evidence of convulsions.

At exploration an obstructive hydronephrosis was found on the right side and an atrophic functionless kidney on the left. A decapsulation and pelviotomy were performed on the right kidney. After operation the patient's condition improved somewhat and the values for retention of nitrogen in the blood decreased markedly, but she died several days later.

In addition to diseases of urologic origin, there are a number of diseases of prerenal or extrarenal origin which cause excessive retention of nitrogenous elements in the blood and to a certain extent simulate chronic glomerulonephritis. These conditions, such as multiple myeloma, pyloric and intestinal obstruction, fevers and inflammation, acute poisoning by mercury, phosphorus, lead or turpentine and renal thrombosis and collapse after severe injuries or after operations, have been well reported elsewhere. Diabetes insipidus at times closely resembles nephritis, particularly when it is of moderate degree and occurs in early childhood. It is of interest that the first patient to whom Rowntree and Geraghty¹¹ gave the phenolsulfonphthalein test was a child suffering from diabetes insipidus, in whom they proved that the renal function was practically nil. At necropsy the case proved to be one of chronic nephritis.

This paper is concerned only with urologic conditions which simulate, and are at times confused with, chronic nephritis.

PYELONEPHRITIS

Pyelonephritis either alone or in association with some other lesion of the urinary tract most frequently resembles, and is most commonly confused with, chronic glomerulonephritis.

In its milder forms, pyelonephritis is seen frequently by the urologist in a form in which it causes few symptoms and only slight renal damage; it persists for years and is marked by more or less frequent exacerbations. It is almost invariably bilateral, and while it occurs usually without demonstrable or evident obstruction to the outflow of urine, it also is present in some degree in most cases of obstruction of the urinary tract and is a causative factor in progressive destruction of the kidney.

In the early stages of the disease the blood pressure is normal or at times slightly below normal. As the disease progresses and more and more renal damage occurs, the blood pressure rises. This is not, however, an invariable occurrence, as in three cases reported by Longcope,¹² wherein the patients died, the blood pressure remained normal. He stated that usually the blood pressure in such cases rises during the latter months or years of the presence of the disease and may reach such high figures as 225 mm. of mercury systolic and 150 mm. diastolic. The blood pressure was above 160 mm. systolic and 105 mm. diastolic in ten of fifteen cases observed by him during the terminal stages of the disease. In half of these cases the systolic pressure was 200 mm. or over, and in ten the diastolic pressure was between 110 and 150 mm.

On examination the eyegrounds usually are normal in the mild forms of the disease. In severe forms

occasional, usually single, hemorrhages or cotton wool patches may be found in the retina. Wagener¹³ stated that these patches are of the type seen in patients with general toxemia or septicemia of any origin and are not characteristic of the renal disease and are not related to the degree of renal insufficiency.

Glomerulonephritis is the only variety of nephritis in which retinitis is common. The retinitis associated with glomerulonephritis commonly is designated albuminuric retinitis; it is characterized by anemia and edema of the disk; generalized, rather dense edema of the retina, usually grayish white; hemorrhages and cotton wool patches, and, in the macular region, the radiating star figure made up of large, thick groups of hard white exudate. This picture is distinct, limited to cases of glomerulonephritis and never found in association with uncomplicated obstructive lesions of the urinary tract. On the other hand, patients with obstructive lesions of the urinary tract, especially those in whom infection is also present, may have chronic glomerulonephritis also, together with all the associated signs of this condition. Longcope¹² reported that three of nine patients who had chronic pyelonephritis and whose disease proved fatal had also associated a chronic diffuse glomerulonephritis.

The urine in cases of pyelonephritis usually is slightly cloudy and frequently shows the slight opalescence associated with bacteriuria characteristic of infections caused by *Escherichia coli*. The specific gravity of the urine is usually low and the urine contains a moderate amount of albumin, many leukocytes and more frequently than not a large number of bacteria. In an occasional case, if the disease is of long duration and the infection mild, when the infection is due to the coccus group, only small numbers of leukocytes may be present or none may be found, but almost invariably bacteria are plentiful in the sediment and positive cultures are obtained. Dr. Tinsdale Harrison¹⁴ demands repeated negative cultures in all cases in which the diagnosis is glomerulonephritis before he rules out infection of the urinary tract and accepts the diagnosis of nephritis. With regard to the urine, the most helpful fact in distinguishing pyelonephritis from chronic glomerulonephritis is that with the former casts are rarely and erythrocytes are only occasionally found. The amount of phenolsulfonphthalein returned is definitely lowered, even with the milder forms of the disease, especially during the periods of exacerbation. When the disease is of long duration, only 5 per cent or, occasionally, only a trace of dye is returned.

An examination of the blood usually reveals a reduction in the amount of hemoglobin, and, contrary to conditions found in the blood in cases of nephritis, there is an increase in the leukocyte count, further evidence of infection.

The concentration of nonprotein nitrogen in the blood is usually elevated above normal and is a good index of the degree of permanent renal damage. In one case, with a return of only a trace of phenolsulfonphthalein in two hours, the concentration of nonprotein nitrogen varied from 70 to 90 mg. per hundred cubic centimeters of blood, for more than two years. Values in excess of 100 mg. are not unusual.

The following case illustrates the difficulties in establishing a diagnosis of pyelonephritis and the similarity between its symptoms and those of chronic glomerulonephritis, as well as the help derived from establishing the correct diagnosis and instituting treatment:

CASE 2.—A man aged 52, who had been sick for four years, had lost 30 pounds (14 Kg.) in the last two years, had been weak and tired and had had frequent headaches. He had voided frequently at night and had occasionally had moderate dysuria.

On physical examination his blood pressure in millimeters of mercury was 160 systolic and 105 diastolic. His expressed prostatic secretion contained a large amount of pus. His blood contained 48 per cent of hemoglobin; the red blood cell count was 3,200,000 and the leukocyte count 12,500. The urine was pale and slightly cloudy and had a specific gravity of 1.007. It contained many leukocytes and bacteria but no casts or erythrocytes. Culture of the urine from the kidney and the bladder yielded *Escherichia coli*. The two hour return of phenolsulfonphthalein was 10 per cent. The concentration of nonprotein nitrogen was 60 mg. per hundred cubic centimeters of blood.

Repeated lavage of the renal pelves; irrigation of the bladder and prostatic massage were carried out, together with the administration of urinary antiseptics. In four months he had gained 20 pounds (9 Kg.), the concentration of nonprotein nitrogen had dropped to 42 mg. per hundred cubic centimeters of blood and the return of phenolsulfonphthalein had increased to 25 per cent in two hours. The urine was much clearer, and he felt in general greatly improved.

He was not seen again until eighteen months later. He had had no treatment in the meantime and most of his symptoms had recurred. He again had lost considerable weight. The systolic blood pressure was 180 mm. of mercury, and the urine contained many leukocytes and bacteria. The return of phenolsulfonphthalein was less than a trace in two hours, and the concentration of nonprotein nitrogen was more than 100 mg. per hundred cubic centimeters of blood on two occasions. No treatment was given at this time.

In this case a number of conditions were suggestive of chronic nephritis—high nitrogen retention, increased blood pressure, and low phenolsulfonphthalein output. The diagnosis was definitely established by data obtained by laboratory examination, by cystoscopy and by the response to treatment as a urinary tract infection. *Escherichia coli* was present in the pelves of both kidneys; the urine contained no casts or erythrocytes and only a small trace of albumin, but many leukocytes, and the blood showed an increased number of leukocytes, evidence of an infectious process.

In an occasional case the various diagnostic features may not be so prominent, and it may be impossible definitely to state that the condition is not pure nephritis; or, as previously stated, the two conditions may overlap.

OBSTRUCTION OF THE UPPER PART OF THE URINARY TRACT

Complete or partial anuria results when the two kidneys are blocked simultaneously, when the ureter to a single kidney is obstructed or when the better of the kidneys is blocked and the other is overloaded. In contrast to the anuria associated with nephritis, the anuria associated with obstruction of the ureter is striking because of the mildness of the early symptoms. The individual patient may continue to enjoy health for several days in spite of voiding only a few centimeters of urine daily. Later preuremic symptoms, such as hiccuping, vomiting and muscular twitching, develop. Rarely is there difficulty in arriving at a diagnosis in

14. Harrison, Tinsdale: Unpublished clinicopathologic discussion, California State Medical Society General Meeting, May 9-11, 1938.

cases of acute obstructive anuria. The previous history of the patient and the associated localized pain suggest the condition present and indicate the need for roentgenographic and urologic investigation. It is the long-standing ureteral obstruction of moderate degree that is not correctly diagnosed and that may be confused with nephritis. Chronic bilateral ureteral obstruction of even moderate severity is usually associated with some infection and at times the picture is one more of infection than of obstruction, but usually it is a combination of the two conditions. On the other hand, extensive destruction of the renal parenchyma rarely occurs from infection alone, without some degree of obstruction of the urinary tract being present.

The association of pressure, atrophy and infection results in renal insufficiency. The picture, especially if the patient is young, is sometimes very similar to that of chronic glomerulonephritis. There are several features which aid in distinguishing the two conditions. Examination of the eyegrounds usually reveals nothing abnormal in cases in which the obstruction appears early in the course of the disease. Even in cases in which the obstruction appears late or is severe, rarely is anything found except the occasional retinal hemorrhage seen in cases of general toxemia. Such hemorrhage is markedly in contrast to the albuminuric retinitis associated with chronic glomerulonephritis. The urine, similar to that seen in cases of pyelonephritis, contains many leukocytes and bacteria, only occasionally casts or erythrocytes and only small quantities of albumin. The blood shows evidence of infection by an increased leukocyte count. The most significant difference between these two conditions is that the patient who has obstruction, even though he exhibits marked retention of nitrogen in the blood, is not as sick as the patient who has chronic glomerulonephritis associated with a similar concentration of urea in the blood. The patient who has obstruction of the ureter is frequently ambulatory and complains only of anorexia, headache and some dizziness; in contrast, the patient who has nephritis is bedfast and stuporous and has convulsions.

The following case is that of a young woman whose condition was diagnosed and treated as glomerulonephritis but was found at necropsy to be bilateral congenital obstruction of the ureter and dilatation of the upper part of the urinary tract:

CASE 3.¹⁵—A woman aged 21, who complained of loss of strength and endurance for one week, four years before had been told that she had Bright's disease. At that time she had lost her sight and had albumin in the urine and her blood pressure was 240 mm. of mercury. She gradually had improved and had been able to do some work until one week before she came for examination.

Some edema of the face and neck was present. Examination of the eyegrounds disclosed numerous areas of pigmentation that were thought to indicate scars due to old hemorrhages. The vessels were more sclerotic than normal. The blood pressure in millimeters of mercury was 188 systolic and 120 diastolic. The urine contained large numbers of leukocytes and a large amount of albumin but no casts and only rarely an erythrocyte. The specific gravity was 1.014. The concentration of hemoglobin was 41 per cent; the red blood cell count was 2,300,000 and the leukocyte count 11,100. The concentration of nonprotein nitrogen was 133 mg., that of urea 113 mg. and that of creatinine 8.5 mg. per hundred cubic centimeters of blood. With rest in bed and a high caloric, high vitamin and low salt diet the patient became steadily worse and died.

Necropsy revealed congenital dilatation of the ureters, with almost complete obstruction at the point where they passed over the brim of the pelvis; bilateral hydronephrosis; acute pyelonephritis, and cystitis.

There are a number of points in this case suggesting the true nature of the condition present, infection of the urinary tract. The leukocyte count in the blood was elevated; there were no erythrocytes or casts in the urine, but there were large numbers of bacteria. The eyegrounds did not have the features associated with chronic glomerulonephritis and showed merely the retinitis associated with hypertension. Finally, a patient who had chronic glomerulonephritis and in whose blood the concentration of nitrogen was similar to that of this patient would be prostrated, possibly comatose, or would have convulsions.

OBSTRUCTION OF THE LOWER PART OF THE URINARY TRACT

Obstruction of that part of the urinary passage which lies below the bladder results most frequently from prostatic hypertrophy, carcinoma, contracture of the neck of the bladder or urethral stricture. Any of these conditions may cause retention of urine, back pressure and renal insufficiency.

For the purpose of this report it makes little difference what the cause of the obstruction may be; the effect on the upper part of the urinary tract is the same. In the early stages of prostatic obstruction, the most common cause of retention of urine in men, increased frequency of contraction of the trigon in attempts to open the vesical orifice causes compression and obstruction of the lower part of the ureter. Obstruction below and peristaltic pressure above result in ureteral and later in pelvic distention. Later there may occur incompetence of the ureterovesical valve, which permits ureteral regurgitation and which converts the bladder, ureter and renal pelvis into one connecting waterway under variable pressure. With dilatation of the pelvis and calices, thinning of the renal cortex and impairment of function result.

With renal impairment, symptoms of uremia appear. If there is also present an infection of part of the urinary tract and more or less pyelonephritis, the symptoms of renal impairment and uremia progress much more rapidly.

In an occasional case the symptoms due to renal embarrassment outweigh the local symptoms of obstruction. The patient may not have definite symptoms of disease of the bladder or he may not include symptoms of disease of the urinary tract among his leading symptoms. This is frequently seen in cases of slow-growing, malignant, prostatic obstruction.

In one case the only complaints were dizziness, nausea and loss of weight. The concentration of nonprotein nitrogen was 110 mg. per hundred cubic centimeters of blood. There was no frequency, nocturia or pain. The patient thought that urination was normal. The prostate gland was small, smooth and fibrotic. The fact that it was fixed, firm and stony gave definite evidence of cancer of the prostate and indicated that disease of that organ was responsible for the condition. A rounded smooth mass, recognized as a distended bladder, could be felt above the pubis. Catheterization revealed retention of 1,000 cc. of urine, promptly relieved the symptoms and permitted the amount of nitrogen in the blood to return to normal.

15. Drs. B. O. Raulston and E. M. Butts permitted me to use the details of this case.

The large amount of nitrogen retained in the blood in such cases may not be due entirely to renal insufficiency. The work of Fender¹⁶ has shown that the mucosa of the bladder when inflamed transmits urea in quantities sufficient to raise appreciably the concentration of nonprotein nitrogen in the blood. If the bladder is normal this does not occur. On the other hand, in most cases in which there is retention of urine in the bladder for long periods there is some mucosal inflammation. In one patient who had residual urine in excess of 600 cc., the concentration of nonprotein nitrogen was in excess of 90 mg. Twenty-four hours after a permanent urethral catheter was inserted the concentration of nonprotein nitrogen was less than 50 mg. Removal of the catheter, permitting retention to recur, caused the concentration of nonprotein nitrogen to return in twenty-four hours to more than 80 mg. Insertion and removal were done on several occasions and caused similar, but smaller, excursions of retention of nitrogen with each trial.

Uremia develops very readily in infants and children if obstruction is below the bladder. The symptoms are more severe and the disease is more rapidly fatal than if obstruction is in the upper part of the urinary tract. Campbell¹⁷ stated that the symptoms and the results of laboratory examination in the preuremic stage of the disease in cases of urinary obstruction in children may not be distinguishable from those of chronic nephritis.

Campbell reported the case of a boy aged 14 months who had bilateral hydronephrosis secondary to congenital hypertrophy of the verumontanum. A diagnosis of chronic nephritis was made. The urine had a low specific gravity and contained albumin and hyaline and granular casts, and the concentration of nitrogen in the blood was increased. The true nature of the condition was noted at necropsy.

In a second case reported by Campbell,¹⁷ that of a girl aged 8 years, a diagnosis of chronic nephritis was made from the laboratory examination. The child was observed for eighteen months, during which time the blood pressure rose from 140 to 230 mm. of mercury. Three months before death occurred, cystoscopy revealed a bilateral ureteropelvic obstruction and hydronephrosis; these conditions were confirmed subsequently, at necropsy.

The diagnosis of most of the obstructive lesions of this type is determined by examination of the urinary tract; if this is carried out, usually there is no particular difficulty in ruling out nephritis. The urine in most cases of obstruction contains many leukocytes, small amounts of albumin and only rarely erythrocytes or casts. In the occasional case of obstruction in which the urine is not affected, the absence of casts or erythrocytes and the slight amount, or absence, of albumin are important diagnostic leads.

Patients who have uremia due to obstructive lesions are seldom likely to have convulsions, although they may have muscular twitchings. They are not very sick, and in general most of their symptoms are less pronounced than are the symptoms of patients who have chronic nephritis and a similar high retention of nitrogen.

POLYCYSTIC RENAL DISEASE

The clinical picture of impaired renal function, hypertension and hematuria in cases of polycystic disease is very similar to that associated with chronic glomerulonephritis, and the diseases are not infrequently so diagnosed. Symptoms of gastrointestinal disorders, such as loss of appetite, nausea and vomiting, are not uncommon, and anemia, headache and weakness may occur. Examination of the urine reveals that it is not unlike that seen in cases of chronic nephritis. The specific gravity is frequently less than 1.010, albumin is always present and erythrocytes may be found. Casts are found in only a small percentage of cases.

A definite impairment of renal function usually occurs before a physician is consulted. There are a decreased output of phenolsulfonphthalein, retention of nitrogenous substances in the blood and decreased ability to concentrate urine. The return of phenolsulfonphthalein was less than normal in 67 per cent of 193 cases reported by Braasch and Schacht.¹⁸ In some of their cases no dye, or only a trace, was secreted. In 67 per cent of 117 of their cases in which the determination of nitrogen was noted, the concentration of urea was more than 40 mg. per hundred cubic centimeters of blood, and in only thirty-three was it normal; in twelve cases it was more than 200 mg. Hypertension occurs early and is usually present when the disease is advanced; cases in which the systolic blood pressure varies from 170 to 200 are not uncommon.

Sclerosis of the retinal arterioles is seen at times; this is of the type usually seen in cases of essential hypertension, and when retinitis occurs it is not different from the retinitis associated with essential hypertension. It usually can be distinguished from the retinitis associated with chronic glomerulonephritis. It is retinitis associated with hypertensive disease and not retinitis associated with nephritis, although the hypertension probably arises as a sequela of the renal lesion.¹³

Differing from patients who have acute obstruction of the lower part of the urinary tract and also from those who have chronic glomerulonephritis, many who have polycystic renal disease have acquired a remarkable tolerance to renal insufficiency. Even if the concentration of blood urea nitrogen is in excess of 150 mg. per hundred cubic centimeters, even if the value for blood creatinine is from 5 to 8 mg. and even if no more than a trace of phenolsulfonphthalein is returned in the urine, patients not infrequently are able to live in comparative comfort for years. Similar signs of a high concentration of nitrogen in the blood if a patient had chronic glomerulonephritis would suggest rapid death.

On account of the insidious onset of polycystic renal disease and the physical accommodation to the condition that has just been mentioned, many patients are not aware of its presence until almost complete destruction of the kidney has occurred. Death is usually due, as with chronic glomerulonephritis, to renal insufficiency, often markedly increased by associated infection of the renal pelvis, which if untreated hastens the process of destruction of tissue. Control of the urinary infection by proper drainage and the administration of urinary antiseptics will do much toward retarding the progress of the usually steadily advancing parenchymal destruction. Regulation of the patient's manner of living, and

dietary precautions, including restriction of intake of protein, may help considerably.

In an occasional case, surgical intervention may help to limit the progress of pain, excessive hematuria or infection. Formation of stone, tuberculosis and tumors occasionally occur in association with polycystic disease of the kidney. Perinephric abscess, having its origin in infected cysts, at times requires drainage. Nephrectomy may be necessary, either to abolish the condition present or to prevent a general infection of the urinary tract. Surprisingly enough, patients with polycystic renal disease undergo the removal of a kidney well, especially those in the second or third decade of life. Apparently at this time there is a certain amount of regeneration of the remaining renal tissue. Walters and Braasch¹⁹ reported thirty-one cases in which nephrectomy had been performed; only one patient died, a man aged 67 who had adenocarcinoma of the kidney. Palliative surgical measures, such as incision and drainage of some of the larger cysts, are also in order in certain cases. Evidence of marked disturbance in function of both kidneys usually contraindicates surgical treatment except as an emergency method.

The chief cause of the destruction of the kidney is pressure atrophy of the parenchyma due to expansion of the cyst. There is marked atrophy of the parenchyma between and around the cysts, together with extensive areas of interstitial fibrosis. The majority of the glomeruli have undergone some hyaline changes, either complete or in patches, due to thickening of the capillary basement membranes.

HYPERPARATHYROIDISM

Hyperparathyroidism, represented either by parathyroid hyperplasia or by definite adenomas of one or more of the parathyroid glands, has long been known to affect the skeletal system and to produce decalcification, cysts, tumors and pathologic fractures of the long bones. More recently it has been shown that it may be the cause also of the formation of stones in the urinary tract and consequent renal insufficiency, together with an associated high value for nitrogen in the blood. The amount of calcium and phosphorus excreted in the urine is so greatly increased in this disease that not only are stones formed in the urinary tract but occasionally the deposits of calcium bodies and calcium infarcts so damage the kidneys that marked renal insufficiency develops. Barney and Mintz²⁰ stated that, as a rule in cases of hyperparathyroidism, formation of stone precedes the formation of lesions of bone, often by a period of several years. It is interesting to observe that in five of the twenty-nine cases reported by these observers there were skeletal lesions alone, while in thirteen the lesions were confined to the urinary tract and in eleven both skeletal lesions and lesions of the urinary tract were present.

Collip²¹ has shown that excessive doses of parathyroid extract administered to dogs resulted, in a few days, in death, which was preceded by anuria and retention of nitrogenous products. The dogs had calcium deposits in various organs, including the kidneys. Albright²² and his co-workers stated that an excessive

amount of the parathyroid hormone in the blood for a few days can so alter the equilibrium that calcium in some form is deposited in the tissues and death ensues. These authors stated that in certain cases of hyperparathyroidism the clinical picture is similar to that of chronic glomerulonephritis. The scarcity of casts in the urinary sediment is a helpful distinguishing point. They reviewed several cases. Höffheinz²³ reported a case in which the clinical diagnosis included "contracted kidneys"; the concentration of nonprotein nitrogen in the blood was 221 mg. and the blood pressure was 85 systolic and 55 diastolic. The patient died in uremic coma. Necropsy revealed calcium bodies and calcium infarcts in the kidney. Besides a large coral-like stone which filled the upper part of the pelvis of the right kidney, there were many small stones in both kidneys. There were marked pyelonephritis and contraction of both kidneys. This case was of interest also in that all parathyroid glands showed formation of tumor.

In a case of McCallum's, reported by Albright, the patient had nausea, weakness and vomiting. Polyuria and nocturia were noted. The blood pressure was 140 and 100. The concentration of urea nitrogen was 185 mg. per hundred cubic centimeters of blood. The urine contained albumin and a few erythrocytes and leukocytes, and the specific gravity varied between 1.007 and 1.009. Both lower parathyroid glands were enlarged (2 by 1.5 cm.).

As to therapy for the prevention of renal damage associated with hyperparathyroidism, Albright²² pointed out that intake of fluids should be forced, that an alkaline reaction of the urine should be avoided, that administration of ammonium chloride and presumably other acidosis-producing salts is contraindicated, that a high phosphorus diet, while indicated for demineralization, imperils the kidneys and should be used only when the blood values can be followed carefully, and that the same rule applies to a high calcium diet, although to a less extent. He expressed the point of view that in almost all cases of this disease damage to the kidney eventually develops unless the condition is corrected by successful surgical measures.

WATER INTOXICATION

Water intoxication must be considered in the contemplation of nephritis and obstruction of the urinary tract. Water intoxication in itself causes symptoms of uremia, restlessness, asthenia, nausea, convulsions, coma and at times oliguria. If the main channel for the loss of water is closed by renal insufficiency or by obstruction of the urinary tract of any type, increasing the intake of fluids might cause a condition of water intoxication. The continued ingestion of water in an effort to cause diuresis and to reduce the concentration of nitrogen in the blood would only tend to increase the state of water intoxication.

On the other hand, surprisingly large amounts of water may be taken if the output is satisfactory. Rowntree²⁴ cited a patient of Trousseau's who had diabetes insipidus whose urinary output was 43 liters a day and whose intake of water was 40 liters. Even with the water exchange at this high level, signs of water intoxication did not appear, probably because of the prompt elimination of the water. Rowntree stated that in all probability it is not the quantity of water ingested

or the rate of exchange but rather an intake of an amount of water greater than the body can excrete that is responsible for the production of water intoxication.

Convulsions caused by water intoxication, when they occur, are general and of extreme potency and frequently resemble those due to strychnine poisoning. Water intoxication terminates in death unless the excessive intake is discontinued. A hypertonic solution of sodium chloride usually gives prompt relief from the symptoms. Rowntree, in his experimental work in an effort to obtain relief of symptoms, gave a hypertonic solution of sodium chloride to a group of dogs in various stages of water intoxication. Some of the dogs which were in a stupor, coma or convulsions improved strikingly within five to fifteen minutes after the administration of the solution; in fact, many of the animals appeared to be practically normal from a half hour to an hour later.

SUMMARY

Various urologic conditions markedly resemble, and not uncommonly lead to the diagnosis of, chronic glomerulonephritis. The most common conditions are infection, obstruction and certain metabolic disturbances. The majority of these diseases are readily recognized if a complete urologic examination is carried out. The similarity of these various urologic conditions to chronic glomerulonephritis leads to a diagnosis of nephritis. The fear that urologic instrumentation might be followed by serious reactions frequently prevents a complete study that would indicate the true nature of the lesion. In truth such fears are in most cases not warranted, as reactions rarely follow cystoscopy, with the present rapid, accurate methods, and the use of recently devised innocuous urographic materials. Carefully and gently carried out, such examinations cause no trouble even in patients with extremely damaged kidneys.

In all cases wherein there is even the slightest doubt as to the diagnosis, the patient should be given the benefit of a complete urologic investigation. If this is thoroughly carried out, a small but definite group of patients whose condition has been diagnosed as chronic glomerulonephritis will be found to have conditions that can be partially or completely relieved.

CONCLUSION

When a physician makes a diagnosis of chronic glomerulonephritis, he should be certain that the kidney itself is the seat of the disease and that the patient is not suffering from a curable condition simulating chronic glomerulonephritis.

1930 Wilshire Boulevard.

Medicine in the Third and Fourth Centuries.—Art, literature and medical knowledge all were slipping steadily backward in this third century. The soldiers in some of the far away provinces set up governments of their own, took barbarian wives, and were ready to resist compulsion from home. Zenobia, in her oasis at Palmyra, defied the Roman legions for years, for "she knew all science, history and military art"; but she was finally conquered and taken to Rome in A. D. 273, to complete the triumph of Aurelian. Her daughter became his queen, and in the next generation Zenobia's grand-daughter became queen of all Persia. She introduced Greek medicine into her medical school founded at Edessa. Indirectly, this helped to save Greek medicine to the world, for the successor of this school at Edessa became the great school of the fifth century at Gondashapur, with its medical library, its famous teachers and its Arab writers.—Hurd-Mead, Kate Campbell: *A History of Women in Medicine*, Haddam, Conn., the Haddam Press, 1938.

CHRONIC STREPTOCOCCIC ULCER OF THE SKIN

UNRESPONSIVE TO LOCAL THERAPY BUT CURED
BY SULFANILAMIDE: REPORT OF
TWO CASES

M. H. GOODMAN, M.D.

Instructor in Dermatology, Johns Hopkins University
School of Medicine

BALTIMORE

Reports of chronic ulcerations of the skin in which the streptococcus plays a primary etiologic role cannot be found in the literature. Fissure and intertrigo with their occasional concomitants chronic recurrent erysipelas and lymphangitis, as Barber¹ pointed out, have been viewed heretofore as the most chronic lesions produced by this organism. The dermatoses of streptococcus origin are mostly acute or subacute and superficial. Even in ecthyma, as Sabouraud² emphasized, ulceration in the true sense does not occur, and as in other streptococcic pustular dermatoses the organism is simply present in the purulent exudate and ceases to act when free drainage and cleanliness by locally applied antiseptics are brought about and maintained for a shorter or longer period.

Fig. 1 (case 1).—Large ulcer on right forearm before treatment with sulfanilamide. The glazed appearance is due to the characteristic unremitting serous exudate.

The type of ulcer which forms the basis for this report is apparently unique in that it was produced by streptococci, presented features of chronicity both clinically and histologically and occurred on the skin of healthy individuals. There is no previously recorded instance of an ulcer presenting the peculiar characteristics found in these cases, and the striking response to sulfanilamide of this type of lesion has also heretofore not been reported.

CASE 1.—History.—L. B., a white youth, aged 19, slender but in robust health, was seen Aug. 12, 1937, for a sore on the anterior surface of the right forearm and a smaller one on the anterior aspect of the right leg at the junction of the middle and lower thirds. There was nothing in the family or personal history relevant to the present illness. The patient stated that in the last week of June 1937 he had sustained insect bites to the arms and legs while in his home. All the bites disappeared with the exception of the ones from which the ulcers developed. These two areas became swollen and were quite red, painful and tender. July 1 he consulted a

Dr. J. Howard Brown gave advice in the bacteriologic studies.

1. Barber, H. W.: *Prognosis in Streptococcal Infections of the Skin*, *Lancet* 2:35 (July 6) 1935.

2. Sabouraud, Raymond: *Ecthyma*, in *La pratique dermatologique* (Ernest Besnier, L. Brocq, L. Jacquet), Paris, Masson et Cie, 1:923-945, 1900.

physician, who incised the swelling on the right forearm and also that on the leg. In both areas open sores developed which did not yield to treatment with various antiseptics, including gentian violet and mercurial applications. The patient stated that a few days after the onset of the lesion on the forearm he noticed slight pain in the right armpit but that there was no diffuse redness or streaks of redness on the arm above the sore at any time. The pain in the armpit vanished in a few

Fig. 2 (case 1).—The result (complete healing) obtained with sulfanilamide on the ulcer shown in figure 1.

days and he had had none since. The lesions became progressively larger and presented a rather curious aspect when first seen by me.

The lesion (fig. 1) on the forearm consisted of an ulcer, roughly oval, 2 by 3 inches (5 by 7.5 cm.) in diameter. The border was irregularly elevated throughout and was separated from the underlying tissues in such a manner that there resulted a marked undermining, at some places to a maximum distance of one-half inch (1.3 cm.). The skin of this uplifted border was ragged, frayed and serrated and with its bright red to dull red halo and induration presented a rather angry appearance. The redness extended in some areas, especially at the upper margin, to a distance of about 1 inch beyond the border, and within this zone there was marked tenderness on pressure. The depth of the ulcer varied from one-fourth to one-half inch (0.6 to 1.3 cm.), and the base presented smooth, grayish red, glazed, flattened, papilliform excrescences which were covered with a thin whitish yellow seropurulent exudate which could be easily wiped away. If wiping was carried out a little too energetically, there would result free bleeding from the granulations. On pressure over the margin of the ulcer a seropurulent fluid could be expressed. The lesion on the leg consisted of an ulcer which was circumscribed and rounded and measured 1 inch in diameter. It presented features similar to those of the lesion on the forearm except that there was less undermining and less redness about the border. This ulcer also discharged a thin seropurulent fluid.

The general physical examination disclosed no positive manifestations. The blood count showed red blood cells 4,710,000, white blood cells 10,100, with a differential percentage of polymorphonuclears 64, basophils 2, small lymphocytes 30, large lymphocytes 2 and transitionals 2. The Wassermann reaction of the blood was negative and an examination of the urine was negative.

Routine Treatment.—In spite of dressings alternately with 3 per cent aqueous-alcoholic gentian violet, a proprietary oxyquinoline benzoate compound ointment, 10 per cent ammoniated mercury ointment and boric acid ointment (U. S. P.), some fresh necrosis appeared in the margin of the ulcer on the forearm and in the adjacent normal skin. Thereafter a regimen of fomentations including warm compresses of 1:1,000 solution of mercury bichloride, 1:3,000 and 1:1,000 solution of potassium permanganate and solution of chloramine-T, 1 per cent, totaling six hours daily supplemented by cleansings with mild soap solutions and interval dressings with 2 per cent ointment of allantoin, ammoniated mercury, boric acid or 3 per cent

gentian violet effected no change over a period of several weeks. During this period a specimen was taken for biopsy from the inner border of the ulcer on the forearm.

Throughout the period of observation the patient occupied himself only with the treatment and spent a good deal of time at complete rest. During a short period of suspended treatment, bacteriologic studies were undertaken.

Laboratory Studies.—Smears made from the serous exudate showed a few gram-positive cocci in chains. Cultures were made on plain agar, beef broth, Loeffler's mixture, blood agar plates (surface inoculation) and desoxycholate agar plates. After forty-eight hours a single type of growth appeared on each of the mediums, with the exception of the desoxycholate agar medium,³ which inhibits the growth of streptococci; this was sterile. All the other mediums showed a pure growth of one and the same organism, which by deep inoculations into blood agar proved to be a beta hemolytic streptococcus. The blood agar surface showed a pure growth of a hemolytic streptococcus. The discovery in the stained smears (fig. 3) from the broth cultures of a tendency for the cocci to be arranged mostly in chains (at least more than six) with only occasional diplococoid formation would, in view of the source of the organism (from a seropurulent and nonerysipelatos lesion) and its manner of growth in bouillon, warrant designating it as *Streptococcus pyogenes longus* by the essentially morphologic classification proposed by von Lingelsheim⁴ in 1891. In spite of the fact that in the light of more recent bacteriologic work the division by von Lingelsheim of *Streptococcus pyogenes* into the group "longus," which is pathogenic, and the group "brevis" (in chains of six or less), which is nonpathogenic, has been proved to be totally arbitrary and unsupported by the facts, the name still persists to the present day in various textbooks to designate the common pyogenic streptococcus of the skin. Brown⁵ clearly showed that the grounds for such a division and labeling are untenable. In the same report he proposed his classification of the streptococci on the basis of their behavior in blood agar and their sugar-fermenting characteristics.

The beta hemolytic streptococcus cultured from the lesions in this case fermented lactose, salicin and trehalose but not mannite, inulin and sorbitol. It was thereby demonstrated to be *Streptococcus pyogenes* of human strain (as opposed to animal

Fig. 3 (case 1).—Streptococci in smear from bouillon culture of exudate from ulcers. This *Streptococcus pyogenes* is still erroneously referred to as *Streptococcus pyogenes longus* because from bouillon culture it appears mostly in chains of at least six or more organisms.

strain).⁶ Judging from its behavior in the tissues, it is of low grade virulence, since it produced no lymphangitis and only a mild transient lymphadenitis.

Sections were prepared with hematoxylin and eosin stain, Verhoeff's elastic tissue stain and the bacterial stain of Brown and Brenn.⁷ There was a marked hyperplasia of the epidermis, most advanced at the edge that constituted the border of the ulcer, decreasing gradually from this point beyond toward the normal skin. In this pseudo-epitheliomatous border the prickly cells for the most part were swollen, unshapely, opaque and

Fig. 4 (case 1).—Section from the edge of the large ulcer on the forearm. The infiltrate is of the chronic fixed tissue cell type with a preponderance of plasma cells and many lymphocytes and large mononuclears.

edematous and their nuclei were shrunken and pyknotic. The papillary bodies were extremely edematous, containing a fibrinous meshwork enclosing a loose infiltrate of lymphoid cells principally, some plasma cells, a few polymorphonuclear leukocytes and an occasional eosinophilic leukocyte. In the cutis proper the lymphatics were widely dilated and filled with a coagulum of serum, and down to the fatty layer the collagenous tissue, elastic tissue and blood vessels had suffered extensive degeneration and displacement by inflammatory cells which just back of the edge of the ulcer consisted of an abundance of polymorphonuclear leukocytes, many degenerated, but beyond this and throughout the section elsewhere of solid focal collections of plasma cells. In places, especially about remains of hair follicles and sweat glands, there was a solid infiltrate almost entirely of plasma cells. Many large mononuclear cells and a few eosinophils were found. However, here and there were seen some fibrin and free blood pigment. Back of the zone of intense inflammation there were a few dilated blood vessels surrounded by mantles of lymphocytes and plasma cells. The inflammatory process, therefore, consisted of a chronic fixed tissue cell type (fig. 4). At some distance beyond the edge of the ulcer and enclosed for the most part within the confines of these monocyctic cells there were revealed by the bacterial stain numerous cocci within phagocytic granulocytes and grouped in pairs and short chains lying free between the cells (fig. 5).

Course of Disease Under Sulfanilamide.—September 29, within forty-eight hours after the institution of sulfanilamide, the ulcers showed a sharp change. The remarkable healing effect on the lesions is outlined in table 1, which is self explanatory. The smaller ulcer was completely healed at least ten days before the larger one. The completely healed large ulcer with smooth, firm scar is illustrated in figure 2.

7. Brown, J. H., and Brenn, Lena: A Method for the Differential Staining of Gram-Positive and Gram-Negative Bacteria in Tissue Sections, *Bull. Johns Hopkins Hosp.* 48: 69 (Feb.) 1931.

CASE 2.—History.—M. F., an unmarried man, aged 29, a Russian-born Jew, slightly undernourished but well developed and intelligent, admitted to the Johns Hopkins Dermatological Clinic Nov. 15, 1937, complained of ulcers on both legs. There had been no tuberculosis in the family and aside from the fact that his mother had a goiter the family history was unimportant. He had always been in good general health. In childhood he had uncomplicated mumps. Following an attack of tonsillitis in 1924 his tonsils and adenoids were removed. In 1926 a gland was removed from the left angle of the mandible. While he was in the hospital for this operation an ulcer developed on the right shin which healed after several months. In 1928 and 1932 a series of small ulcers appeared on both legs, in each instance healing after several months. The last attack was associated with open sores on both ears, which healed with scars.

The patient's habits were fairly regular and until the onset of his present illness he had been employed as a salesman for a wholesale stationery store, which required that he be on his feet continuously eight hours a day.

The present illness began in the first week of June 1937, when a "red bump" appeared almost simultaneously on the lower third of each leg. These areas broke down into open sores, which gradually enlarged into discharging ulcers within about three weeks. At this time he came under competent medical management, but in spite of routine general measures and continuous local treatment of the ulcers, including the application of fractional x-rays, ultraviolet rays, various antiseptic fomentations, stimulating agents such as tar oils, and protective and antiseptic ointments, the lesions slowly increased in size until his admission to the Johns Hopkins Dermatological Clinic. His physician personally communicated his opinion that the ulcers were probably tuberculous. At no time in the course of the disease had there been lymphangitis or femoral or inguinal lymphadenitis to an appreciable degree.

Examination.—The general physical examination was negative except for the presence of a deflected nasal septum and posterior nasal discharge. A roentgenogram of the chest was negative.

Fig. 5 (case 1).—Section shown in figure 5, stained with Brown and Brenn's bacterial stain. Numerous cocci within phagocytic granulocytes and grouped in pairs and short chains between the inflammatory fixed tissue cells.

In general the skin and accessible mucous membranes were of good texture and color. There were a few tiny depressed scars in the margins of the ear lobes. In the anterior triangle of the neck on the left side was an irregular elongated hypertrophic scar. Over both legs there were a number of superficial

scars varying in size up to a half dollar (30 mm.). There was a moderate cyanotic tint of the legs when dependent, and numerous superficial varicosities were present. The dorsalis pedis artery was barely felt in each extremity.

Rather symmetrically occupying the inner aspect of the lower third of each leg and extending down slightly to the anterior and posterior surfaces was a large roughly circular ulcer about the size of the palm (fig. 6). The border was mostly serpiginous but at a few points its outline was jagged, dentate or angulated. The base was very uneven and presented in places glazed rough granulations which protruded to the level of the border but in other areas formed depressions or gullies which reached a depth from the surface of the skin of as much as 2 cm. The entire edge of the border was inflamed, but in some zones it was only slightly so, smooth, thin and well attached to the base, whereas in others it was thickened and infiltrated, quite angrily red, rough, necrotic looking and undermined. This infiltration and redness extended in places to a distance of 1 cm. beyond the edge. The base of the ulcer was covered with a copious yellowish thin seropurulent exudate, which one could express from the undermined portions by pressing on the overlying skin. Slight pressure over the border or base of the ulcer elicited tenderness, but there was no spontaneous pain. On each leg just above the large ulcer there was a superficial one, the size of a half dollar, exuding a copious serous fluid. The patient stated that these ulcers had appeared in the last few weeks. There was no enlargement or tenderness of the femoral or inguinal lymph glands.

Laboratory Studies.—At the time of admission the Wassermann reaction of the blood was negative and examination of the urine was negative. The blood count showed red blood cells

tory process of the same nature as that found in case 1, but the chronic features were exaggerated in that the plasma cell and lymphoid cell infiltrate was accompanied by numerous discretely and solidly grouped large mononuclear cells to such a degree that a competent dermatopathologist who also saw the patient felt very strongly that the condition might be tuberculous.

Course of Disease Under Sulfanilamide.—After the patient received three 20 grain (1.3 Gm.) doses of sulfanilamide daily

| | | January 16-22..... | 40 |
| | | January 22-February 8..... | 20 |

After three days of treatment, healing commenced in all the ulcers; it is probable that by Nov. 27, 1937 (see text) only minimal doses were necessary because the progressive healing was uninfluenced by the increased doses which were given from Nov. 28, 1937, to the date of complete healing of the large ulcers on Feb. 8, 1938.

for three days (a total of 180 grains or 12 Gm.) the undermining in the borders in most areas was obliterated, the discharge was free from pus and consisted of a thin, straw-colored serous fluid, and its quantity was definitely reduced. The borders of the ulcers also appeared thinner, lost their necrotic appearance in most places and looked healthier. Treatment with the drug is outlined in table 2. After the third day of treatment healing set in at the borders of the ulcers and progressed slowly but surely. To note the effect of increased dosage, the patient, November 28, began to ingest a daily total dosage of 60 grains (4 Gm.) divided into three 5 grain (0.3 Gm.) tablets four times a day. The various levels of dosage by this schedule, as noted in table 2, were maintained for unusually prolonged periods. The only changes that occurred in the ulcers consisted of a further diminution in the quantity of discharge, but healing at the margins progressed at the same pace as previously. The small ulcers healed within two weeks from the commencement of sulfanilamide therapy. By December 30 the large ulcers were reduced to something less than half their original size. The patient appeared in excellent physical condition, having gained 12 pounds (5.4 Kg.). Aside from a slight nausea for a few days after the institution of sulfanilamide therapy, which was overcome by sodium bicarbonate taken only for a short period, he exhibited no cyanosis or other toxic effect. On this date examination of the blood for methemoglobin was negative, and the cell count showed red blood cells 5,300,000, hemoglobin content 97 per cent, white blood cells 5,700, with a differential percentage of segmented neutrophils 64, basophils 1, lymphocytes 28, and monocytes 7.

Throughout the period of sulfanilamide therapy local treatment for the ulcers consisted only of simple boric acid ointment dressings, changed every four days. Beginning Jan. 4, 1938, the use of gentian violet 2 per cent aqueous solution and oil of cadeberry on the ulcer of the left leg failed to produce any appreciable difference in the rate of healing of the two ulcers.

At this time it was felt advisable to see whether any special benefit would accrue by raising the intake of sulfanilamide to at least the maximum standard dosage originally advocated by Long and Bliss⁸ for severe infections in order to attain

| 14-16..... | 45 | |
| 17..... | 45 | At least 5/6 of ulcer closed with smooth scar—small central dry crust remaining |
| 18-20..... | 30 | |
| 21..... | 30 | Entire ulcer healed except for pea-sized area in center |
| 22..... | 30 | |
| 23-31..... | 15 | |
| November 1-2..... | 15 | |
| 3..... | 15 | Complete healing with smooth scar |

The small ulcer on the right leg completely mimicked in appearance and course the large ulcer before and during the administration of sulfanilamide. The former was completely healed October 25.

5,120,000, hemoglobin content 100 per cent, white blood cells 9,900, with a differential of juvenile neutrophils 2 per cent, segmented neutrophils 68 per cent, basophils 2 per cent, lymphocytes 19 per cent and monocytes 9 per cent. The tuberculin test was strongly positive to 0.001 mg. and 0.01 mg. of tuberculin.

The bacteriologic result was the same as that in case 1, with the minor exception that the streptococcus in this instance fermented trehalose more slowly.

Microscopic study of a biopsy specimen obtained from the border of the large ulcer on the left leg revealed an inflamma-

quickly a blood level of 10 mg. per hundred cubic centimeters. Beginning January 9, such increase in dosage was made but no added benefit resulted. By January 18 the ulcers were reduced to the size of a half dollar. Culture mediums of the same type as those originally used were inoculated with the serous exudate of each ulcer. Within twenty-four hours all the mediums were overgrown with *Staphylococcus albus*; there was not a single colony of streptococci. The ulcers were completely healed on February 8 (fig. 7).

COMMENT

In each of two cases there was introduced into the skin a variety of beta hemolytic streptococcus capable of producing a low grade necrosis leading to chronic ulceration. The organism proved to be a *Streptococcus pyogenes* of human strain. When accidentally transferred to the normal skin, it produced an area of redness and edema which softened and became necrotic. The resulting ulcer was superficial and when treated early with locally applied antiseptics healed quite rapidly. However, if not interfered with the streptococcus apparently invades deeply to produce undermining with slowly progressive extension of the ulcer. In both cases the ulcers had enlarged with an irregular, firm, thickened, angrily red, ragged, undermined border and uneven deepening of a roughly granular glazed base, discharging continuously a copious serous fluid. Other than a slight and transient regional lymphadenitis, there were no complications. The biopsy studies revealed the presence of intracellular and extracellular cocci in pairs and short chains, and in various types of mediums inoculated with exudate from the ulcers a pure culture of the streptococcus was obtained. This fact is of particular interest because, as Barber¹ has so emphatically stated in his discussion of streptococcic infections of the skin, streptococcic lesions always become secondarily infected with staphylococci, whereas staphylococcic lesions usually remain pure.

Fig. 6 (case 2).—Large ulcer on left leg, showing undermined border and uneven base covered with serous exudate.

In case 1 it was totally impossible to effect healing by means of local antiseptic treatment. This was unquestionably due to the fact that the organisms, enclosed in a chronic fixed tissue cellular infiltrate in the region of the undermined portion of the ulcers, were beyond the reach of the agents applied. The sharp and prompt effect of sulfanilamide on the ulcers in case 1 not only solved the problem of therapy but gave confirmatory evidence that the ulcers were of primary streptococcus (beta hemolytic) etiology.

The ulcers of the leg in case 2 were each about four times the size of the large ulcer of the right forearm in case 1. The effect of sulfanilamide on these ulcers was as sharp and prompt as in case 1. The dosage of the drug used at the commencement of treatment in case 2 was based on the experience with case 1, and it can be safely assumed that sterilization of the lesions took place as a result of the initial "course" of sulfanilamide, ranging from a total daily dosage of 60 grains to the gradually reduced dose of three 5 grain tablets

Fig. 7 (case 2).—The result (complete healing) obtained with sulfanilamide on the ulcer shown in figure 6. Note the residual scaliness over the small freshly healed area.

a day (table 2). The slower healing in case 2 as compared to that in case 1 was obviously due to the larger size of the ulcers in the former case and to their location on the lower extremities, and the presence of numerous varicose veins in that case.

CONCLUSIONS

1. The complete records of two cases of a hitherto unreported type of primary ulcer of the skin produced by a beta hemolytic streptococcus are added to the literature on streptococcic infections.
2. This type of ulcer is characterized by its pronounced chronicity and extreme resistance to local treatment.
3. Clinically the ulcer presents a markedly inflamed, slowly necrosing, undermined, mostly serpiginous border with a deep uneven and glazed, roughly granular base discharging continuously a copious thin yellowish serous fluid.
4. Histologically the ulcer presents a chronic fixed tissue cellular reaction.
5. Prompt cure of the ulcers in the two cases was brought about by sulfanilamide, which exercised a strikingly specific effect.

NOTE.—Since completion of this article a third case has been observed. A white woman, aged 23, in excellent general health by hospital survey, complained of a group of five large confluent ulcers on the left leg and three on the right leg which failed to respond to continuous medical management with intensive local treatment for several months. These lesions proved to be essentially identical to those reported clinically, histologically, bacteriologically and in their response to sulfanilamide. Also a fourth case of similar type was observed, which, because of unavoidable circumstances, could not be followed with respect to sulfanilamide therapy.

RECENT STUDIES ON EXPERIMENTAL
LOBAR PNEUMONIA

PATHOGENESIS, RECOVERY AND IMMUNITY

O. H. ROBERTSON, M.D.

CHICAGO

I. PATHOGENESIS

Very little is known concerning the optimum conditions for the inception of lobar pneumonia in the human being. That some disturbance in pulmonary function precedes the onset of this disease in the majority of cases seems probable in view of the frequency of antecedent acute infection of the upper part of the respiratory tract, but the manner in which such infection lowers the resistance of the lung to invasion by pneumococci can only be conjectured. Furthermore, in a considerable number of instances lobar pneumonia occurs during a period of apparent good health. An experimental approach to this problem has been carried on in several ways. My associates and I sought to determine first whether or not variations in individual resistance to the different types and strains of pneumococci might be related to the inception of infection. An earlier study of the pneumococcus-killing activity of the blood of various animals revealed the presence of marked species differences in the exhibition of this property. The blood of pneumococcus-resistant animals was found to be capable of killing great numbers of pneumococci, while that of susceptible species either lacked pneumococcidal power or showed it to only a slight degree.¹ This action of the blood was found to depend entirely on the opsonic content of the serum. Leukocytes of susceptible animals were just as active as those of resistant ones in the presence of a potent opsonic serum.²

While the pneumococcidal action of the blood (serum and leukocyte mixtures) did not represent the entire mechanism of natural immunity to the pneumococcus, it did provide a means for determining the factor of humoral immunity in the human being. Tests on the blood of a group of normal persons showed that there exist fully as marked individual variations in respect to the pneumococcus-killing power as were found between the different animal species.³ This observation suggested the possibility that persons contracting pneumonia might belong to the group without demonstrable pneumococcidal action in the blood. Accordingly observations were made on the blood of patients with pneumonia early in the course of the disease, in certain instances from four to six hours after the onset of the illness. The tests showed great divarication. Some of the patients were found to possess no blood-killing power for the pneumococcus causing the infection, while

others exhibited this property to a normal degree. We have no proof that the normal pneumococcus-killing activity was present in the same degree immediately before infection, yet repeated observations on normal persons and on patients suffering from various types of infection of the respiratory tract (studied by Graeser and Harrison⁴) have shown that this characteristic of the blood does not fluctuate rapidly. Hence it seems fair to assume that lobar pneumonia can occur in the presence of a normal pneumococcidal activity of the blood, and this suggests that the inception of the pneumonic infection depends more on some local change in the lung than on fluctuations in general antipneumococcic resistance.

These observations lead to a more detailed consideration of the pathway by which pneumococci gain entrance to the lung. There can be little doubt in view of the accumulated evidence, both clinical and experimental, that the pneumococci producing pneumonia are implanted in the lung by way of the air passages, and that particulate matter may be carried to the terminal air sacs can be inferred from the finding of carbon and other particles in the alveolar macrophages. Also it is known that the lung possesses a remarkably efficient mechanism for the elimination of inhaled material. This consists of the ciliary activity of the bronchial mucosa, the alternate expansion and contraction of the bronchi with each respiration, together with a possible peristaltic contraction of the air tubes, and the cough reflex. Thus foreign material taken into the bronchi is fairly easily eliminated, but if it enters the alveoli expulsion is much more difficult, since neither the alveoli nor the ducts leading to them are provided with cilia or musculature and the bottle-like shape of the terminal air sac offers additional obstruction to egress. However, the alveolar macrophages present in small numbers in the normal lung are capable of disposing of most kinds of inspired substances. Under normal conditions the clearing functions of the lungs are so efficient that the lower part of the respiratory tract is kept practically sterile.

Is there any evidence that interference with the normal eliminatory mechanism of the lung has an important role in the inception of lobar pneumonia, and what effect may the so-called predisposing factors exert in this respect? While some of these factors, such as the inhalation of irritating and poisonous gases and of anesthetics, partial drowning and the inspiration of various sorts of material during operation, in all probability produce a disturbance of the lung's clearing function, pneumonias following such disturbances constitute a relatively small proportion of cases of this disease. The one condition which precedes pneumonia in the great majority of cases is the common cold.⁵ What action a cold may have on the eliminatory mechanism of the lung can only be surmised, although in certain cases in which the infection has reached the lower part of the respiratory tract local obstruction of the smaller air passages may well occur. However, the effect of chilling of the body surface during a cold does seem to have a more direct relationship to the

6. The striking predisposing factor of epidemic influenza may be similar to that of the cold but not unlikely represents a general irritation or injury of the respiratory tract.

onset of pneumonia, since many patients give a history of such an occurrence immediately before the inception of the disease. Here again the nature of the disturbance caused by chilling is not altogether clear. Certain effects on the mucosa of the upper part of the respiratory tract, such as a fall in surface temperature and vasoconstriction, have been observed by Mudd and his co-workers⁷ to accompany depression of the temperature of the skin in the human being. Nedzel⁸ has shown a similar lowering of the temperature of the respiratory mucosa as far down as the lower part of the trachea in experimentally chilled dogs.

PRODUCTION OF EXPERIMENTAL LOBAR PNEUMONIA IN THE DOG

Making use of the conception that local obstruction of the air passages and chilling create conditions suitable for the onset of pneumonia, we proceeded to devise a method for the production of experimental pneumonia in the dog, with doses of pneumococci somewhat comparable to those which might be supposed to cause the disease in man. The dog seemed to be a suitable animal, since its blood exhibits about the same degree of pneumococcidal action as that of the average human being. Small quantities of pneumococcus culture of type I or II were suspended in a starch-broth medium of about the viscosity of sputum and injected through a radiopaque catheter inserted into a terminal bronchus with the dog under the fluoroscope. The animal had previously received a dose of morphine sufficient to lower the body temperature from 4 to 6 degrees F. The larynx was cocaineized to prevent coughing. In this manner it was possible to produce constantly a lobar pneumonia in the dog which closely resembled the disease which occurs spontaneously in man.⁹ The average course of the disease was three or four days. Recovery often occurred by crisis. When doses of less than 0.01 cc. of culture were employed the disease occasionally failed to develop, but well marked pneumonia resulted from as little as 0.00001 cc. of culture. With the smaller doses, from 0.001 to 0.02 cc., the pathologic process usually remained confined to a single lobe and the animal recovered. With larger doses, 0.05 to 0.1 cc. or more, spread from lobe to lobe took place and the mortality rose with the increasing size of the infecting inoculum. Bacteremia, leukopenia and extension of pulmonary involvement were found to have the same prognostic significance as in human beings.

EVOLUTION OF THE CANINE PULMONARY LESION

A study was then undertaken of the changes occurring in the pulmonary lesions from the time of their inception until recovery or death.¹⁰ The animals were killed at varying intervals by means of the rapid intravenous injection of pentobarbital sodium. Within an hour after the implantation of the infecting dose of pneumococci at the periphery of the lung the micro-organisms were seen to be lying principally within the air sacs embedded in the starch, but already they were

observed to be migrating away from the focus of infection. One of the early reactions to the growth of the pneumococci in the lungs is the outpouring of edema fluid into the air spaces. This has been observed by Loeschke¹¹ in human beings with pneumonia and by Rhoads and Goodner¹² in rabbits with experimental dermal pneumococcal infection. While the exudation of edema is a protective mechanism on the part of the body, presumably an attempt to dilute the toxic substances elaborated by the growing pneumococci, it also has the effect of dispersing the micro-organisms in the tissues.

A recent study by Sutliff and Friedemann¹³ has shown that the pneumococcus during its growth produces a substance which when injected into the lungs or under the skin causes a local outpouring of edema such as occurs during pneumococcal infection. The pneumococci are probably spread through the lung to a certain extent by the lymph channels. However, they are

Fig. 1.—Section of lung of a dog killed just after recovery from experimental lobar pneumonia ($\times 625$). The greatly thickened alveolar wall contains many large mononuclear cells, which are becoming detached to form macrophages of the resolution exudate.

seldom seen in the alveolar walls after the first hour or two, and many of the micro-organisms which appear to be in the septal tissue are actually adhering to its surface, as can be shown by a technic devised by Loosli.¹⁴ Our observations would indicate that the pneumococci are carried chiefly in the infected edema fluid, which can pass along the air ways and also from air sac to air sac by means of small apertures in the walls, the pores of Cohn. Until the recent observations of Macklin¹⁵ and particularly the experimental work of Loosli¹⁴ there was much difference of opinion as to whether these communicating openings were artefacts or normal structures. Loosli has shown con-

clusively by means of ingenious experiments that they are normal structures. He has demonstrated in the lesions of experimental pneumonia bands of fibrin passing through pores with contained pneumococci.

Sections taken from the infected lung during the early stages of the experimental disease show that the inflammatory lesion spreads in a fairly regular fashion. Adjoining the normal tissue is an outermost zone of edema-filled air sacs containing many pneumococci. Following the outpouring of edema fluid is a migration of red blood cells and polymorphonuclear leukocytes into the alveoli, and the latter begin to phagocytize the micro-organisms. This constitutes a second zone nearer the central, or original, site of infection, where the concentration of leukocytes is greatest. Here the pneumococci are fewer in number and all within the cells where they undergo digestion. Since the process of phagocytosis takes time, an interval elapses between the arrival of the leukocytes and the ingestion of the

Fig. 2.—Section of consolidated lung from a person who had lobar pneumonia ($\times 700$), showing beginning macrophage reaction; the thickened alveolar wall contains numerous large mononuclear cells which protrude into air spaces. The intra-alveolar cellular exudate is still predominantly polymorphonuclear.

pneumococci. This permits the further peripheral spread of the infected edema fluid and affords an explanation of the problem as to how pneumonia can spread in the lung in the presence of a normal pneumococcus-killing power of the blood. If this is the correct interpretation of the mechanism of the extending lesion it should be possible by accelerating the process of phagocytosis and digestion locally to check the spread of the infection. This we have been able to do by injecting a high concentration of opsonins and leukocytes with the infecting dose of pneumococci. The lesions resulting from this procedure were very circumscribed and soon became sterile.¹⁶

The question then arose as to whether the successful production of lobar pneumonia by the method described depended principally on interference with the eliminatory function of the lung or on the implantation of the

pneumococci in the terminal air sacs. Earlier observations on dogs showed that the simple injection of small amounts of pneumococcus cultures even into the bronchi only occasionally resulted in infection, and this was of a mild nature.¹⁷ In an attempt to answer this question Hamburger¹⁸ has carried out a series of experiments in which suspensions of pneumococci were forcefully sprayed into the main bronchi of morphinized dogs. While this work is not yet completed the results in general suggest that obstruction of the terminal bronchi is the more important of the two factors.

Our finding that with experimental canine pneumonia the size of the infecting dose bears a direct relationship to the inception and outcome of the disease raises the question as to whether dosage may be an important factor in determining the development of lobar pneumonia in the human being. Suggesting this possibility are the observations of Webster and Hughes,¹⁹ who have shown that the numbers of pneumococci in the upper part of the respiratory tract often increase greatly during a cold, but other epidemiologists have not observed such a direct association. However, Smillie and Leeder²⁰ found a higher incidence of the more pathogenic pneumococci, types I and II, in pneumonia contacts with colds than in normal contacts.

II. RECOVERY

The changes observed in the pathogenesis of the pneumonic lesion in the dog are in every way analogous to those seen in the various stages of early primary and young metastatic processes observed post mortem in cases of human lobar pneumonia.²¹ The further development of both the canine and the human lesions proceeds in the same manner. At first the polymorphonuclear leukocytes are able to digest the pneumococci but later in the course of the disease they seem to lose this function, as numbers of normal appearing micro-organisms are visible within the cells and many are free in the younger parts of the inflammatory process. This is the usual picture just before recovery. With the onset of recovery a sudden change occurs, in which the pneumococci in the lungs are rapidly destroyed and the disease terminated. The only known means by which pneumococci are disposed of is phagocytosis and intracellular digestion. Hence it seems evident that in order to bring about a rapid termination of the infection the body must either develop a marked increase in the so-called natural antipneumococcal processes present before and often during infection or develop a new type of reaction. Supporting the latter alternative is the fact that in most cases of lobar pneumonia both in adults and in children the blood develops at about the time of recovery a much greater pneumococcus-killing power than it possessed formerly or is present in normal human beings. This property

17. This result is quite different from that obtained by Blake and Cecl, who produced lobar pneumonia in monkeys by the intratracheal injection of very small doses of pneumococcus culture (Blake, F. G., and Cecl, R. L.: Studies on Experimental Pneumonia: Production of Pneumococcus Lobar Pneumonia in Monkeys, *J. Exper. Med.* **51**: 403-444 [April 1920]).

21. The recent study of experimental pneumococcal lobar pneumonia in the rat by Gunn and Nungester indicates that the evolution of the murine and that of the canine lesions are also essentially the same (Gunn, F. D., and Nungester, W. S.: Pathogenesis and Histopathology of Experimental Pneumonia in Rats, *Arch. Path.* **21**: 813 [June] 1936).

16. Robertson, O. H.: The Effect of Increased Antipneumococcal Immunity on the Inception of Experimental Lobar Pneumonia in the Dog, *J. Exper. Med.* **66**: 705-727 (Dec.) 1937.

depends on the presence of acquired heat-stable opsonins. While these newly produced immune substances undoubtedly play a part in the process of recovery, it has not been possible to assign to them the primary role in this mechanism, since in some instances they are not detectable in the blood until several days after recovery or may appear two or three days before the end of the disease. In not more than half the cases does their occurrence in the blood coincide exactly with the onset of recovery.²² The best evidence for the effective action of such immune substances is the results obtained in the serum treatment of early pneumonia. However, if treatment with serum is begun after the disease is well advanced the infection in most instances persists until the usual time of recovery or death.

Our studies of the pneumonic lesions of dogs killed at the time of recovery have brought to light another mechanism which appears to play an important part in this process. At the beginning of recovery there occurs in the infected lung a striking histologic transformation. The alveolar walls become thickened, owing to the presence of large mononuclear cells, which first protrude into the air spaces and then become free and enter the exudate as actively phagocytizing cells, macrophages (fig. 1). They engulf the red cells, polymorphonuclear leukocytes and pneumococci, which they digest rapidly. Associated with their advent is solution of the fibrin, thinning of the intra-alveolar exudate and resolution of the lesion.²³

MACROPHAGE REACTION IN HUMAN LOBAR PNEUMONIA

The next step was to determine whether or not the cellular change which we have designated as the macrophage reaction occurred in the human lung at the time of recovery from pneumonia. This we were able to do only indirectly, by a study of the resolving areas in lungs examined post mortem. Microscopic examination of such tissues revealed the presence of a well marked macrophage reaction. Furthermore, the beginnings of this process were found in areas which were still intensely consolidated (fig. 2). The different stages resembled in every respect the changes observed in the dog.²⁴ Of great interest was the finding that wherever the mobilization of macrophages was marked the pneumococci were few or absent. Sometimes a single lobe in the state of resolution appeared to be entirely freed of pneumococci while a younger lesion showed micro-organisms in great numbers. The macrophages appeared to be capable of engulfing and digesting large numbers of pneumococci, but the polymorphonuclear leukocytes at this stage appeared to have lost their digestive activity. Whether this is the only method by which the body disposes of the invading micro-organisms we do not know. Curphey²⁵ has bridged the gap between our experimental observations and the postmortem studies by means of biopsies performed on the lungs of patients during the course of

lobar pneumonia. He showed that the cellular reactions which we have observed in the resolving lung after death occur during recovery.

PHAGOCYTIC AND DIGESTIVE ACTIVITY OF MACROPHAGES VERSUS POLYMORPHONUCLEARS

We undertook a study of the phagocytic and digestive activity of macrophages, comparing them with polymorphonuclear leukocytes, both in the test tube and in vivo. Suspensions of macrophages were obtained by injecting acacia into the pleural cavity of dogs. The polymorphonuclear leukocytes were secured by similar injections of aleuronat. These cells were washed free from their native fluid and added to opsonic fluids of varying concentration containing pneumococci. The difference between these two types of cells with respect to their ability to phagocytize and digest pneumococci was striking. The macrophages took up the micro-organisms promptly and digested them so rapidly that sometimes within an hour or two all the pneumococci had melted away within the cells. On the other hand, the polymorphonuclears acted much more slowly, often taking many hours to accomplish the same result, and unless the concentration of opsonins was sufficiently high complete digestion did not occur. Identical results were obtained when pneumococci were injected into the chest cavities containing the two kinds of exudates and samples withdrawn for study at frequent intervals.

It was found, furthermore, that macrophages obtained from dogs highly immune to the pneumococcus were quite unable to engulf pneumococci without the presence of opsonins. This observation is important in relation to the mechanism of recovery, since it indicates that the macrophages appearing at the termination of the disease are not different from the cells of the normal animal and are dependent on opsonins for their action.

RELATIONSHIP OF MACROPHAGE REACTION TO MECHANISM OF RECOVERY

The data thus far presented, while suggesting the importance of the macrophages in the mechanism of recovery, do not exclude the possibility that the local cellular reaction is secondary to some more fundamental change which affects the pneumococci so that the macrophages can dispose of them. We sought evidence on this point in various ways. Occasionally in the dog suffering from experimental pneumonia, clearing or resolution of one, usually the initial, lesion occurs while spread is taking place in another lobe, a phenomenon sometimes observed in human beings. Half a dozen such animals were killed during the active phase of the disease to determine the state of the lung undergoing this local recovery.²⁶ Cultures from the excised lungs showed that the clearing lesion was sterile while the youngest spreading one contained pneumococci. Sections of the lungs showed in the newest lesion the typical appearance of a spreading process, with great numbers of pneumococci free in the edema fluid, while in the oldest clearing lesion, sterile on culture, a marked reaction of the macrophages was found. No acquired immune substances were detected in the blood of any of these animals, which suggested that the appearance of the macrophages was the determining factor in the process of local recovery.

25. Curphey T. J.: Preliminary Report of Intra Vitam Biopsy Studies of the Pathogenesis of Pneumococcus Lobar Pneumonia, *Proc. Am. A. Path. & Bact.* 11: 861-862 (April) 1935.

26. Robertson, O. H., and Coggeshall, L. T.: Local Recovery in Experimental Pneumococcus Lobar Pneumonia in the Dog, *J. Exper. Med.* 67: 597-608 (April) 1938.

However, further observations showed that the process of recovery was of a more complex nature. In an extensive series of autopsies on dogs which had died at different lengths of time after the inception of the disease, a macrophage reaction was found in some part of the pulmonary lesion in the great majority of instances provided the animal lived longer than two days. With few exceptions the reaction became more pronounced and widespread with the increasing age of the pathologic process and was accompanied by a progressive diminution in the numbers of pneumococci, whereas micro-organisms persisted usually in large numbers in the lesions or parts of a lesion where this cellular change failed to occur. In certain dogs which died after four or more days the consolidated lobes were found to be in a well advanced stage of resolution, with the alveolar exudate consisting almost entirely of macrophages, but the animals died with vast numbers of pneumococci in the blood.²⁷ This would indi-

Fig. 3.—Section from the lung of a dog killed four or five days after recovery from experimental lobar pneumonia (X 450) showing subsiding macrophage reaction with a number of free macrophages and others attached to alveolar walls.

cate that the lung possesses great innate powers of recovery. Given a sufficient length of life the lung seems to be able to free itself largely or even completely of the invading pneumococci despite their persistence in the blood stream. It is clear from these observations, however, that the macrophage reaction constitutes only a part of the mechanism of recovery. There is undoubtedly another factor, which may be designated as a generalized process in contradistinction to the local cellular reaction in the lung and which acts to localize the infection and prevent or control invasion of the blood. This general process we may assume involves in part the pneumococidal power of the blood, since loss of this property during the disease is accompanied by bacteremia. There must, however, be other factors operating as well, since occasionally in animals and also in human beings bacteremia occurs despite the presence of pneumococcus-killing activity in the blood.

Because of our ignorance of its nature we may term this the lung-blood barrier. The mechanism of recovery from lobar pneumonia in the dog so far as we understand it may be indicated as follows:

The mechanism is of a dual nature:

1. Local process: macrophage reaction in the lung + ? local production of immune substances.
2. General process: (a) pneumococcus-killing power of the blood; (b) lung-blood barrier.
 - A. If both processes are effective, recovery results.
 - B. If either process fails, death ensues.
 1. Complete clearing of lungs but pneumococci in the blood = death.
 2. Sterile blood all through the disease but absence of macrophage reaction = death.

ROLE OF ACQUIRED IMMUNE SUBSTANCES

Whether or not acquired immune substances play a significant part in the mechanism of recovery in the dog is not clear, since these substances are not often detectable at this time in the blood of the dog. When they do occur it is subsequent to recovery. We have certain evidence for believing that these immune substances are produced by the cells which give rise to the macrophages, and it may be that they are manufactured in the lung, their presence in the blood indicating an excess production and overflow. Except for the difference in the frequency with which acquired immune bodies are detectable in the blood of human beings and dogs, observations to date would suggest that the mechanism of recovery is essentially the same in the two species.

III. IMMUNITY

Until very recently little has been known concerning immunity following recovery from lobar pneumonia because of the paucity of data on the pneumococcus types which cause recurrent infections. The important contribution of Finland and Winkler²⁸ in 1934 gave for the first time definite information on this subject. They found that one attack of the disease does not confer permanently increased resistance against subsequent infection with the homologous type of pneumococcus but that a second attack of pneumonia rarely occurs within a year. Our studies on experimentally induced pneumonia in the dog showed that one attack confers on the animal increased resistance against a second infection which persists for many months at least. The basis of this heightened immunity appeared to consist principally in a marked acceleration of the macrophage reaction in the inflammatory lesion.²⁹ This study was further extended to include observations on repeated infections in the same lobe versus infection in a hitherto uninvolved portion of the lung, with the purpose of determining whether or not an attack of the disease left the affected part more resistant than other areas. In order to make such tests we infected dogs with very large doses of pneumococcus culture, doses from which the normal animal died with a fulminating disease within twenty-four hours. If this inoculum, 5 cc. of culture, followed by mucin to obstruct its expulsion, was injected into the recovered lobe five days after the termination of the disease the animal survived after a brief and limited infection, while the same dose injected into a previously

uninvolved lobe at the same time after recovery resulted in fulminating infection and death, indicating that the factor of high resistance lay within the recovering lobe. If, however, injection into the recovered lung was delayed until two weeks after recovery the dog died. An association between these effects and the presence of macrophages was provided by a histologic study of the lungs of dogs killed at varying intervals after recovery. At the end of five days the recovered lung still possessed a large concentration of interalveolar macrophages (fig. 3). From this period they diminished, until at fifteen days the lung had resumed its normal appearance.

Repeated infection in the same lobe resulted in a much extended duration of the local immunity. After five or six infections the animal survived the test dose, given three to four months after the last attack of pneumonia. But if this dose was injected into a hitherto uninvolved, opposite lobe between fifteen and twenty-five days after the last infection, the animal died. Microscopic examination of the lungs of dogs after recurrent unilateral infection showed in the recovered lobes a certain amount of residual macrophage mobilization, which may have accounted for the prolonged local immunity.

SUMMARY AND CONCLUSIONS

1. By implanting pneumococci suspended in a starch-broth paste into the terminal air sacs it has been possible to produce in the dog a lobar pneumonia which closely resembles that which occurs in the human being.

2. The pneumococci are dispersed from the locus of implantation principally by the edema fluid of the early lesion, which spreads peripherally through the contiguous air passages and the pores of Cohn.

3. The evolution of the inflammatory lesion of the canine disease is essentially the same as that observed in human lobar pneumonia.

4. At the time of recovery a striking histologic change occurs in the pulmonary lesions of both man and the dog. This consists in the transformation of certain of the fixed tissue cells into free macrophages which engulf and destroy the pneumococci much more effectively than do the polymorphonuclear leukocytes. The macrophages are dependent on opsonins for their antipneumococcal activity.

5. The mechanism of recovery appears to be of dual nature, consisting of a generalized process, which acts to localize the infection and prevent or control bacteremia, and a local process, the macrophage reaction, whereby the lung is enabled to rid itself of the invading micro-organisms. If both processes are effective, recovery results. If either one fails, death ensues.

6. One attack of experimental pneumonia confers an increased resistance to subsequent infection which lasts for many months. The basis of such immunity seems to reside in the greatly accelerated macrophage reaction characterizing the recurrent lesions.

7. After recovery a high degree of local immunity can be demonstrated in the involved lobes; it persists only as long as the macrophages are present in the alveoli. However, the duration of the local immunity is greatly prolonged by repeated infection in the same locus. Under such circumstances a residual mobilization of macrophages is observed in the tissues of the lung.

LEPROSY OF THE UPPER RESPIRATORY TRACT

DISCUSSION OF EARLY AND MODERATELY ADVANCED CASES

FORREST J. PINKERTON, M.D.

Attending Ophthalmologist and Otolaryngologist, Leahi Home (Tuberculous)

HONOLULU, HAWAII

Leprous processes may simulate the changes that take place in the mucous membrane affected by subacute and chronic processes of more common occurrence. Though it is believed that the incidence of leprosy is very low in continental United States, there is ample evidence that cases of it are passing through well conducted clinics under improper labels, and the facility with which transportation is carried on with countries of the Pacific, Mexico, Central America and South America foster the introduction of the disease in spite of the screen of ship quarantine inspection.

It has been my privilege and opportunity over a period of seventeen years to observe and study the conditions of the eye, ear, nose, throat and larynx of practically every patient certified as leprosy in whom the diagnosis was proved by painstaking investigation in the Receiving Hospital for leprosy patients at Honolulu, to which an average of from fifty to seventy new patients are admitted annually, and in which there have been between 125 and 200 in residence for periods of from one to eight years. I have also examined, studied and treated large groups of patients among from 450 to 600 in the Settlement at Molokai during these years, by periodic visits of from seven to fourteen days' duration on many occasions.

CLASSIFICATION

The traditional classification of leprosy has been made on the preponderance or presence of clinical evidence and is differentiated by three types, nodular, maculo-anesthetic and mixed. A more current grouping has been made on a similar basis and distinguishes cutaneous and neural cases. During the past two years much discussion has arisen over classifying cases in which there are lesions that have been named tuberculoid lesions or leprides. The clinical type of the case is of interest to the rhinologist and laryngologist because of the accompanying changes in the mucous membranes. However, similar manifestations may appear in cases of different types. The latter observation is in keeping with the view of the authorities who regard the disease as a general infection in which neural, cutaneous and tuberculoid lesions occur and represent only the phases or degrees of the same pathologic process.

PATHOLOGY

The essential histopathologic change of the disease is the involvement of the nerves, skin and mucous membranes by inflammatory processes which are characterized by perivascular infiltration with round cells and

Read before the Section on Laryngology, Otology and Rhinology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

The extent and degree of the studies and observations in leprosy on which this discussion is based were made possible through the cooperation and assistance of the officers of the United States Public Health Service, who have served as the medical staff at Kalihi Hospital, Honolulu, and the adjoining United States Leprosy Investigation Station. Much of my study has resulted from the stimulating influence, council and advice of Dr. N. E. Wayson, formerly director of leprosy investigation at Kalihi Hospital.

by a localized or diffuse "myxedematous" infiltration in which "foam cells," histiocytes and giant cells occur in varying frequency and number. Distributed through many of these infiltrations, in intercellular and intracellular locations, are single or clustered bacilli which are acid fast to stains. The aggregation of these infiltrations constitutes the granuloma of leprosy, or the leproma. Granulocytic leukocytes are found only infre-

Fig. 1.—Total destruction of septum with sinking in of the nasal tip.

quently in uncomplicated lepromas, and the central necrosis or colliquation which occurs in the granuloma of tuberculosis is rarely seen. The infiltrations appear primarily in the perineural and intraneural supporting tissues, in the deeper layers of the skin and in the tunica propria and submucosal layers of the mucous membranes. As they progress they invade the entire structures and distort or destroy them or, on the other hand, probably through interference with their innervation or nutrition, stimulate hyperplasia or cause them to atrophy. Thus follicles and glands of the skin and glands of the mucosa usually become atrophied, or even completely obliterated ultimately, but may become hyperplastic during a stage of the process. Destruction of the elastic elements and the formation of scar tissue result in a flabbiness and a thinning of the membranes. Epithelium may become hyperplastic, thickened or keratinized, and its appearance suggests that produced by other chronic irritations. On the contrary, it may be thinned out to a single layer of cells which is easily brushed off and leaves a denuded surface. The extension of the process beyond the membranes is of particular interest in the nose and larynx because of the contiguity of the deeper layers of the membranes with the perichondrium of the septum, laryngeal cartilages and stroma of the vocal cords.

The gross pathologic appearance seen in the mucosae is that of thin, pale, dry membranes, diffusely thickened, reddened, soggy membranes or nodular thickenings of similar nature, both with and without ulceration. Invasion of the cartilages mentioned is followed by their atrophy or destruction, as observed in the frequent perforations of the nasal septum.

COURSE

It is characteristic of leprosy to present many acute phases and many spontaneous recessions. In the nose, the disease progresses by stages of activity and recession. A severe acute reaction with nasal blocking, edema and swelling may occur and last for several weeks and be followed by recession to an almost normal condition. During these apparently quiescent periods the nose may appear relatively normal, but close examination will

reveal minor changes of the nature indicated on either the septum or the inferior turbinates. This acute attack may not recur for several weeks or months, but each time it occurs the structures become more and more infiltrated, nodular and ulcerated, and the normal tissues are replaced by the lepromatous mass or, as healing takes place, scars, distortions and narrowing of the passages develop. Similar processes occur in other mucous membranes.

Pain is not a constant symptom in leprosy but may be agonizing and persistent during the acute attacks of leprous fever (leprous reaction) for periods of several days or even weeks. The neuritic pain in the face, arms, hands, feet and back are much more severe than the pain of an acute "break-bone fever."

The onset of leprosy is apparently insidious in most cases but occasionally seems to be ushered in with an astonishing suddenness. Its course, when once it is established, is seldom one of uninterrupted steady progression but rather that of advances and recessions. Probably in few cases are attacks of leprous fever or acute reactions of more or less severe degree escaped. It is to be remarked that even with the advanced and extensive manifestations there is little suffering from pain in other than the attacks of neuritis or arthritis. These may occur during the attacks of leprous fever as accompaniments of the cutaneous eruptions previously mentioned. When present, the pain along the course of the peripheral nerves in the arms, hands, legs and feet may be most severe and resistant to sedatives of such potency as morphine. These acute reactions with neuritis, giant urticaria, cutaneous edema, swollen, bluish red hemorrhagic mucous membranes, eyelids closed by edema, with photophobia and streaming tears are distressingly impressive to the medical attendant. However, they usually persist in such intensity for relatively short periods and are often succeeded by recessions of the lesions and prolonged periods of apparent quiescence, though they may be the initiation of steadily progressive changes.

Fig. 2.—Total destruction of the cartilaginous septum with similar mass of granulation tissue replacing the nose.

It is also not unusual to see very advanced lesions of a more chronic type, which appear to be destined to a chronic and destructive course, subside in a few weeks to such a degree that even a fairly critical examination of the patient by one who is inexperienced may result in failure to detect the disease.

These fluctuations in the course and manifestations in the skin and nerves have parallels in the mucous membranes and structures of the nose and throat.

However, though edema may subside, nodules recede and ulcers heal, there are scars, atrophies, distortions and mutilations remaining in proportion to the severity of the process and to the structure or function of the tissues affected.

CLINICAL OBSERVATIONS

Nasal.—Careful studies of the mucous membrane will reveal that practically every leprous patient has some nasal lesion due to leprosy. This opinion is concurred

Fig. 3.—Nodular infiltration of uvula with extension into the right supratonsillar fossa.

Fig. 4.—Nodular infiltration of the soft palate.

in by many observers, among them Del Rio,¹ who showed that "the nose was affected in 82 per cent," although he does not state the type of case.

The symptoms that the patient presents are those of dryness, stuffiness, excessive crusting, blocking and epistaxis. All these conditions may be present in modified form in children, but epistaxis and nasal crusting occur most often. The epistaxis may be the most significant complaint to bring the patient to the physician and is undoubtedly influenced by nose picking among children. As the child reaches adolescence, the symptoms are prone to increase markedly, since active leprosy is evidenced more during this period of life and in young adults. Among mature and older adults the symptoms may be those of the complications and sequelae of the more active processes.

The conditions observed within the nose tend to vary in accordance with the predominant clinical manifestations. Among the neural types the mucous membrane is swollen, pale, dry or relatively dry during active progressions, and it is not uncommon to note practical freedom from pain on manipulation of the nasal membranes. Ulceration is not common in the primary neural types, but it does occur in those nodular cases in which healing has occurred and which have become residual or secondary neural forms. Perforation of the septum is frequently found in this secondary neural type, with atrophy and crusting that closely resembles the *ozena* so familiar to all rhinologists. However, there is no assurance that the *ozena* of leprosy is of specific leprous origin.

Among the nodular types the mucous membranes are markedly reddened, or a bluish gray. They are usually moist but may be dry and present evidence of deep infiltration and nodulation. The membranes impress one as soggy and are covered with crusts, either with or without ulceration, and have a tendency to bleed with the slightest trauma. The principal sites of the nodules are the anterior third of the septum and

the anterior half of the inferior turbinate. They are also found on the lateral walls. The middle turbinates seem to be involved less frequently.

The sinuses do not appear to be attacked by the disease, and I have not seen a case of sinus disease that seemed to be caused by a definite extension of a leprous process rather than indirectly by the results of the process within the nose or by other conditions. Though the long bones of the hands and feet are frequently included in the leprous processes, it is uncommon to find the changes in the flat bones such as those of the nose.

Murdock² made a survey at Kalihi Hospital of fifty cases in which there was marked involvement of the soft tissues of the nose but observed no instance of involvement of the nasal bone.

With the cartilaginous septum, however, it is quite different, since large perforations occur in it and extend as far forward as the tip. I have seen several cases in which the entire cartilage had been perforated and destroyed and the nasal tip had become a loose, flabby and formless mass of tissue (figs. 1 and 2).

As healing proceeds, much scarring occurs and may be accompanied by great distortion. The intranasal structures may become adherent by dense synechiae and crusting, and the nasal passages may be completely obliterated. Partial or complete collapse of the alae may result from paralysis of the elevators of the wings and angle of the mouth in lesions of the seventh nerve.

Acute leprous reactions with marked edema of the nasal mucosa, sudden epistaxis and edema of the face, ears, neck and extremities may occur. These acute reactions are accompanied by high fever, chills, agonizing neuritis and arthritic pains and efflorescence of cutaneous lesions, varying from those of morbilliform character, erythema nodosum or acute cellulitis, and may be complicated by acute swollen nerve trunks and evidence of acute arthritis.

Pharyngeal.—There is a remarkable freedom of symptoms with leprous involvement of the pharynx unless the patient is suffering with an attack of "acute leprous reaction." More rarely the palatal muscles may

Fig. 5.—Showing the progress forward of the infiltration of the soft palate.

Fig. 6.—Much infiltration and distortion of the entire hard palate.

Fig. 7.—The alveolar processes of the upper central incisors showing extensive involvement.

become progressively paralyzed during the very late stages of the disease and cause the characteristic regurgitation of fluids through the nose and the nasal voice.

Definite changes in the mucous membrane are rarely observed among the neural types. During the acute attacks of leprous reaction the palatal muscles may become paretic or paralyzed, and with the subsidence

1. Del Rio, A. L.: Clinical Contribution to the Study of Leprosy of the Ear, Nose and Throat, *Ann. di laring., Otol.* 36: 80-88 (Feb.) 1936.

2. Murdock, J. R.: Leprosy: Observations on the Nose and Throat, unpublished paper read before the Honolulu County Medical Society, July 3, 1931.

of the attack there may be an astonishing return of function. Nodular types frequently present changes in the mucous membranes of the pharynx. Nodules commonly occur in the earlier stages at the base of the uvula (fig. 3), extend into the folds above the tonsils and subsequently spread over all parts of the soft palate (figs. 4 and 5). In later stages they spread forward over

Fig. 8.—Large nodular formation of the right half of the anterior tip of the tongue.

the hard palate (fig. 6) and form broad ridges of nodular infiltration along its center even to the alveolar areas (fig. 7). The teeth become loosened and are partially buried by the nodules. On the other hand, the lingual surface of the alveolar processes of the upper central incisors is frequently involved early in this process, and the extension of the infiltration is backward along the ridge of the palate.

The nasopharynx shares in the process by extension, and nodules may be seen high on the posterior nasopharyngeal wall in those cases in which the thickened soft palate does not interfere with examination by the mirror.

Lingual.—Few symptoms are complained of in leprosy lesions of the tongue. Neural involvements of the tongue are not seen, but nodules are (fig. 8), usually in the anterior third and late in the disease. Leukoplakia is also quite common in the same location and occurs late. These areas of leukoplakia are often quite anesthetic to tactile stimulus. Ulceration occurs when nodules have broken down, though they are usually quite superficial. Rao³ describes "macroglossia" in which, instead of definite nodules, the whole tongue may be enlarged owing to a generalized infiltration of the whole organ, which he feels corresponds to the "leontiasis" type of cutaneous lesion affecting the whole face. I have not seen this type of lesion, but I have seen thickened and deeply furrowed tongues (fig. 9), which may be analogous.

Del Rio¹ states that "the tongue was affected in 20 per cent, nodules being observed in 15 per cent and cicatrices in 5 per cent," but my patients have not shown so high an incidence of these lesions.

Tonsillar.—As a result of our studies⁴ and subsequent observations we have concluded that more than 20 per cent of leprosy patients have demonstrable infiltrative and nodular lesions of the tonsils (fig. 10) which are of leprosy origin because of specifically proved associated changes.

Laryngeal.—Approximately 40 per cent⁴ (substantiated by subsequent observations) of the moderately advanced nodular cases present leprosy lesions of some form in the larynx, and in the vast majority of instances the epiglottis is involved. A great majority of the more advanced cases present laryngeal lesions. The characteristic early symptom is "the leprosy huskiness," a

peculiar vocal quality that strikes the experienced as suggestive. The patients complain of a dryness and a tickling sensation that causes a dry, unproductive cough.

The mucous membrane of the neural type is dry and a grayish red, and the surface is often covered with a frosty exudate which is thin enough to allow the red membrane beneath to shine through. It does not become ulcerated as in the nodular type, but it may become atrophied to some extent. The latter observation has apparently been noted also by Sechi and Giunti,⁵ who state that "in neurotic leprosy, however, one will find only the usual atrophic alterations." In the early nodular type the epiglottis is attacked early on both its anterior and posterior surfaces (fig. 11) and extension occurs into the surrounding parts by contiguity along the aryepiglottic folds, the arytenoids and posterior commissure. In early cases the anterior parts appear to be affected first, but in the later stages one may see a dull, gray, nodular tissue within the entire larynx. The arytenoids stand out in the process later by becoming almost immobile, large and hard with infiltrations (fig. 11). Single large nodules form characteristically along the lateral border of the epiglottis. The cords become swollen when nodules involve the lateral bands, as often happens, and the nodules commonly invade the ventricles and vallecule. Nodules in the cords are probably more common than is known, but they are seen rarely because they occur late, when the distortions and infiltrations of the structures above obscure their observation.

The recurrent laryngeal nerve escapes in most cases (except during an acute reaction), while the superior laryngeal nerve is involved more often by deep infiltration in its branches of distribution. I have never seen a case of recurrent paralysis of the nerves which I was sure was due to leprosy. The motor nerves innervating the muscles of the upper part of the respiratory tract are seldom affected in other than very late cases.

Congestion, swelling, infiltration, nodulation, ulceration, atrophy and scar formation with contractures and

Fig. 9.—Broad ridges with deep furrows and islands of leukoplakia involving the entire tongue.

Fig. 10.—Extensive nodular infiltration of the right tonsil.

distortions are the successive steps in the disease in the larynx as in all the other diseased parts of the mucous membrane.

Not infrequently in leprosy patients a severe edema of the larynx develops resembling that of some "allergic" phenomena in intensity and degree. Laryngeal stridor and edema of the glottis may occasionally result in fatal consequences. This acute reaction is also accompanied by high fever, chills, severe pain in the limbs and acute cutaneous lesions of many forms.

DIAGNOSIS

Though the diagnosis of leprosy can be made in many instances by clinical examination, it can be confirmed in most cases by bacteriologic examination. This can be made easily and quickly by the rhinologist with microscopic preparations.

The technic of making a nasal "snipping," which follows is comparatively simple: Use a semisharp

Fig. 11.—The epiglottis infiltrated with nodules throughout its entire anterior and posterior surface and the arytenoids extremely enlarged and infiltrated with hard nodules.

Freer submucous elevator under good illumination, press firmly enough to blanch the tissues under the blade and scrape hard enough to get some of the epithelium, since the bacteria are in the tissues; hence swabs collecting mucus are valueless unless ulceration is present. Spread the collected scrapings on a slide and stain by the Ziehl-Neelsen method of staining for tubercle bacilli. The favorite site for scraping is the septum, near the anterior border, or on the side of the nose immediately above the anterior end of the inferior turbinate. Blood in the specimen makes a poor microscopic preparation, and the attendant trauma may leave an intractable ulcer; hence bleeding should not be provoked.

Murdock² examined 164 patients by the foregoing method and 143, or 87.2 per cent, gave positive bacteriologic results, which is a higher percentage than would give positive results with cutaneous snips.

The same technic may be carried out when practicable in the examination of the pharyngeal lesions. When a well defined nodule exists in the soft parts, any form of ring punch may be used to remove the entire nodule for biopsy. This procedure may excite an intractable ulceration which might not otherwise occur; hence excision of a nodule of the mucous membrane should be resorted to only in unusual cases.

As a rule I depend on swabs for collecting bacteriologic specimens from the larynx. I have used the punch on nodules of the epiglottis, but here again there is the danger of starting up an ulcerative process.

In the event that these examinations of the nose and throat are undesirable, because of any of several reasons, contributory evidence of the presence of the disease may be obtained by "snipping" the skin of the lobe of the ear, even though no definite changes are detected in it. Snippings from the ear are easily carried out and yield reliable results if properly executed. I have found the best technic to be as follows: Grasp the lobe of the ear or the nodular area firmly between the thumb and finger of the left hand to blanch the tissue; have an "ever-ready" reinforced back safety razor blade with a single cutting surface in the right hand; with the toe or point of the cutting edge, make a small nick into the area about 3 mm. deep, and while the blade is still buried in the tissues twist it out at right angles to the line of incision, carrying with it some serum and tissue cells wherein the bacteria are located.

In the event of failure to confirm the diagnosis in suspected cases by examination of the local lesions and the ear, one should make an inspection of the entire body, looking for associated lesions and making microscopic examinations of those cutaneous lesions observed. The skin of the brow and of the buttocks is affected very frequently, and the lesions found in these areas are often more advanced than those in other locations.

DIFFERENTIAL DIAGNOSIS

Leprosy is commonly mistaken for syphilis and until later years it was common experience to find that leprosy patients had had much antisyphilitic treatment before a diagnosis was finally made. This mistake was made because such a great number of leprosy patients gave a positive Wassermann reaction. More than 40 per cent of leprosy patients show a positive Wassermann reaction in the nodular types without a history or other evidence of syphilis. I have observed negative Wassermann reactions on admission of leprosy patients to the hospital and have also observed that as the leprosy disease progresses the Wassermann, Kahn and other precipitation tests become positive and that the intensity of the test diminishes as the leprosy recedes. In the U. S. Public Health Service conference in which serums were submitted to Kolmer, Kahn, Eagle and originators of other tests, the results were as described.

Wayson,⁶ who studied the subject at Kalihi Hospital, thinks that "most cases of advanced nodular or myxedematous types will yield positive serology." No evidence has been submitted to prove that patients with the neural type (except those secondary to the healed nodule) give more positive tests than other members of the general population of the same age, race and manner of living.

The therapeutic test may be resorted to in doubtful cases, but even this is not proof of syphilis. In the administration of arsenicals the leprosy condition may recede as in syphilis, though much more slowly. However, leprosy frequently recedes spontaneously without therapy of any sort and likewise after administration of intravenous treatment with nonsyphilitic agents.

A detailed word picture of the appearance of leprosy changes in the mucous membranes is difficult and one unconsciously forms conclusions from clinical "hunches" and experience with numbers of cases of the two other diseases whose underlying pathologic condition is classified as a granuloma, namely syphilis and tuberculosis. I have had limited experience with laryngeal syphilis but have been fortunate through my association as attending laryngologist to an active hospital of 450 beds for tuberculous patients to be able to make comparisons between the tuberculous and the leprosy process. Then too, many leprosy patients have tuberculosis. In

Fig. 12.—Advanced nodular infiltration with destruction of the central portion of the epiglottis.

6. Wayson, N. E.: Personal communication to the author.

fact it is a common coincident infection and the two diseases are frequently present at the same time.

Leprous, tuberculous and syphilitic lesions of the larynx may resemble one another at one stage of their development.

Tuberculosis almost always involves the posterior part of the larynx first, and the most frequent site is the posterior commissure. The arytenoids, folds and epiglottis are involved later.

Leprosy involves the epiglottis first and the cords and arytenoids later. The anterior and the posterior surface of the epiglottis are affected alike. Tuberculosis is almost always very painful while leprosy is characteristically almost painless. In the earlier stages the mucous membrane is more hyperemic in tuberculosis and syphilis, while in leprosy it is pale and gray. Tuberculosis is bilateral as a rule; syphilis is usually unilateral and almost always involves the anterior structures, while leprosy may be either and when seen late is widespread, involving several parts. Syphilis quickly ulcerates, the ulcer being sharply defined with clearcut edges, the surrounding areas being smooth and highly congested. The larynx wherever involved with leprosy is definitely nodular, though ulceration may occur. When ulceration occurs, aided by secondary infection, the epiglottis may be destroyed (fig. 12). However, one does not see the great destruction of tissue in laryngeal leprosy that one sees in tuberculosis or syphilis, with the same amount of nodular involvement. Leprosy tends to heal, and scars cause distortions in one area while the adjoining area is actively infiltrated with nodules. A leprosy larynx may be intensely nodular and infiltrated and not break down, while in tuberculosis and syphilis no such extensive nodular infiltration takes place without early deep ulceration and breaking down.

While a differential diagnosis can be made in most cases, there are times when all local signs fail and one

must depend on examinations elsewhere in nerves, skin and chest and in serology and bacteriology.

Care must be observed in making the bacteriologic diagnosis and it is sometimes necessary to resort to bacteriologic cultural methods, since staining and morphologic characteristics are not sufficiently exact to differentiate the bacillus of leprosy from that of tuberculosis.

Even animal inoculation may be misleading since the development of large lymph nodes containing acid-fast organisms may occur after inoculation with either of these bacteria. *Bacillus tuberculosis* grows readily and characteristically on suitable mediums. The bacillus of leprosy has probably never been grown on artificial mediums.

The presence of nasal deformities present striking differential points. I speak of the so-called saddle nose.

If the bony septum is destroyed and absorption of the nasal bones occurs in syphilis, one may expect to find a sinking in or depression of the nose (fig. 13).

In leprosy the bony septum is not destroyed; only the cartilaginous portion is involved, and in this type the nose sinks nearer the tip (fig. 14).

It has been reported that the hard palate may perforate, but I have never seen a case which I considered

Fig. 14.—Leprous deformity of the nose characterized by destruction of the septal cartilage and sinking in of the nasal tip.

was due to leprosy; syphilis yes, tuberculosis perhaps, but leprosy no.

TREATMENT

After having tried many of the remedies, including the heralded chaulmoogra oil, I have concluded that none of them act as a specific in local or topical treatment. Hygienic care of the mucous membranes, which resolves itself largely into methods of cleansing, and the accomplishment of drainage in the nose appear to assist uncomplicated healing and certainly give comfort to the patient. This general conclusion was reached after controlled experimental treatment which I carried out several years ago⁴ on another large group of patients and has seemed to be substantiated by subsequent observations.

I have found that the patient who rests his larynx has less cough and irritation than one who indulges in talking and other vocalizing which amount to abuses of his larynx. I have used the spray of chaulmoogra oil directly into the larynx without favorable results. The use of bland oils by inhalation of the fine spray seems agreeable to the patient. Finally, the treatment of leprosy of the upper part of the respiratory tract is much the same as that of treating the same parts in a tuberculous patient, and, since the condition of the nose, throat and larynx reflects to a great extent the general condition of the patient, the treatment should in the main be directed toward improving the general condition.

ABSTRACT OF DISCUSSION

DR. R. W. BURLINGAME, San Francisco: Having had the privilege of caring for the lepers for the San Francisco health department for the last twenty-one years, I find the observations on leprosy of the mucous membranes of the nose particularly interesting. These membranes are an aid to diagnosis and have been discussed for the past forty years, first by Stecker in 1897 at the International Leper Conference held in Berlin that year and later by Plummet, Falcao, Brinkerhoff, Holman and others. I believe this is the first report of so many cases over such a long period by a trained rhinologyologist. Most of the earlier reports deal with the finding of the *lepra bacillus* in the nasal secretions; others advance the theory that the initial lesion of

Fig. 13.—Characteristic nasal deformity, saddle nose, due to syphilis.

leprosy occurs in the nose. Dr. Walter Brinkerhoff's conclusions were that examination of the nasal septum was of no value in the diagnosis of incipient leprosy. I believe that not a few lepers might be discovered early in the disease by nasal examination in nose and throat clinics dealing with Islanders, Orientals, Central Americans and East Indians, were the findings of Dr. Pinkerton kept in mind. This is important from a public health standpoint, as this is the most infectious period of the disease. Fortunately, with one or two exceptions, European races in the temperate climates have built up a comparative immunity against this disease. On at least two occasions in the last few years we have received lepers at the Isolation Hospital, where the tentative diagnosis was made in nose and throat clinics in which the patient applied for treatment because of nasal symptoms alone, there being nothing on the exposed surfaces of the skin to suggest leprosy at the time of examination. After the condition was found in the nose and acid-fast organisms were demonstrated by the microscope, a more thorough examination with the patient undressed disclosed well defined macules and ulnar nerve enlargement of early neural leprosy. These very early cases are usually of the neural type and are not noticeable until the patient is undressed, because the usual contractures and deformities of the hands have not had time to develop, whereas the nodular or cutaneous type of leprosy usually occurs on the ears, face, brows or neck, where it is plainly discernible before nasal symptoms become troublesome.

DR. RALPH A. FENTON, Portland, Ore.: It is unfortunate that time limitation made it impossible for Dr. Pinkerton to give this splendid paper in its entirety; I think it should be read by all of us on the Pacific Coast who happen to be seeing people who come off the various vessels that come across the Pacific or from the South Seas. It is particularly important to us. It is also important to men who are practicing in New Orleans or in Texas and the Gulf ports. A good many of these cases slip by. They are picked up by the United States Public Health Service occasionally, but it is very important that the summation of the work of twenty-five years that Forrest Pinkerton has given should have a prominent place in the literature and should become a bible to those of us who practice in the seaports of this region.

DR. FORREST J. PINKERTON, Honolulu, Hawaii: I should like to stress the point Dr. Burlingame brought out. We are not concerned with the diagnosis of the advanced case. The layman on the street does that. The doctors are guilty of allowing these patients to go on misdiagnosed for a matter of months. In my paper I refer to that. It has been common experience to find patients who have been treated for syphilis for a year or two years during these earlier stages of the disease. The positive Wassermann reaction is used often as a single criterion in diagnosing syphilis, but it is known that approximately 40 per cent of leprosy patients will show a positive Wassermann reaction at one time or another without a history or other evidence of syphilis. Another thing that should be stressed, as Dr. Burlingame brought out, is the importance of stripping the patient: undress him, do not use artificial light, use good daylight and you will be surprised what you see when examining these unexplained lesions; you may discover other infiltrative lesions around the area of the malar eminence and commonly on the buttocks, the favorite sites for the macular types. The anesthetic type, of course, is more difficult and one must use the tactile heat and cold technic and all the other finer technics that come from special study.

Thyroxine the Watchdog of Metabolism.—Less than a thousandth of an ounce of iodine is all that stands between you and imbecility. It is the principal constituent of thyroxine (distorted from the Greek, meaning "I rouse to activity") which is the watchdog of metabolism. Without thyroxine we should be as brainless and inactive as vegetables and far less beautiful, and it takes iodine to make thyroxine. If the soil contains enough iodine there is an ample amount in the food. In places where the soil is deficient in iodine the food and water are also deficient, and the inhabitants have goiter.—Furnas, C. C., and Furnas, S. M.: *Man, Bread and Destiny*, New York, Reynal & Hitchcock, 1937.

THE PSYCHOANALYTIC TREATMENT IN A SANATORIUM OF CHRONIC ADDICTION TO ALCOHOL

ROBERT P. KNIGHT, M.D.

TOPEKA, KAN.

There is perhaps no other condition met in psychiatry in which there is so much confusion of treatment methods, so much interference by the relatives and so many cases of relapse after attempted treatment as in chronic alcohol addiction. Also there is perhaps more pessimism with regard to this condition among those who attempt the treatment of unselected alcoholic addicts than with regard to any other psychiatric condition. Those who, like the laymen-therapists Durfee, author of "To Drink or Not to Drink," and Chambers, co-author with Dr. Strecker of "Alcohol—One Man's Meat," elect to treat only those addicts who themselves desire and seek treatment and are willing to cooperate, are still able to discuss the subject optimistically, but they give no evaluation of statistical results over a period of time. This paper will deal with the attempt to apply psychoanalytic knowledge to the study and institutional regimen of chronic alcoholic addicts and psychoanalytic technic to the individual treatment of such patients. I shall not attempt a statistical summary of all cases treated at this institution (the Menninger Sanitarium) but shall confine myself to my personal experience with twenty male alcoholic addicts seen in the past five years, of whom eleven were in psychoanalysis for varying periods.

SELECTION OF CASES AND ADMISSION TO THE SANATORIUM

There has been no selection of favorable cases in the series on which this discussion is based. There is an implicit selection from a certain social and financial stratum, however, since only those patients are dealt with who can afford, or rather whose parents can afford, moderately expensive institutional fees. Nineteen of the twenty patients came under pressure varying from parental insistence and threats of divorce action by their wives, which resulted in pseudovoluntary admission, to being brought by force by relatives, physicians and attendant, or deputy sheriff, often by deception, and deposited drunk in the institution. With these intoxicated, unwilling patients it is our policy to begin immediate medical care directed toward whatever physical condition is found, with immediate withdrawal of all alcohol. The psychiatric struggle begins when such a patient begins to sober up. His typical reactions of anger at incarceration, demanding of freedom and privileges, and protestations that he has now learned his lesson and won't drink any more are met with the consistent attitude on the part of physicians, therapists and nurses that his history clearly indicates a need for psychiatric study in a controlled and restricted environment and that such freedom as we may be able to give him later will depend on such study and observations. This period of "beating against the bars" may last from a few hours to many weeks, but however long it lasts the same consistent attitude is maintained toward him, and attempts are constantly made to obtain his own history, as detailed a history as possible having already been secured from relatives or the referring physician.

From the Menninger Clinic.
Read before the Section on Nervous and Mental Diseases at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

If, as rarely occurs, an alcoholic addict with his own financial resources comes to the institution seeking treatment, he is told frankly of the restrictions that will be a part of the treatment and is bluntly informed that he will not like it and will want to leave. He is also told that any adequate treatment will require many months. If he decides to enter, knowing such factors in advance, the outlook is better, because half the battle is won if there is a sincere desire for help.

PSYCHIATRIC STUDY AND EVALUATION OF THE CASE

It is recognized by all psychiatrists who have studied persons chronically addicted to alcohol that the alcoholism is only a symptom, not a clinical entity, and that while there are certain personality traits common to most alcoholic addicts, the drinker's deeper psychologic conflicts and environmental distress are strictly individual and vary as widely as do similar factors in various neuroses and psychoses. Superficial impressions to the contrary, no excessive drinker is normal and well adjusted when sober. It is the purpose, therefore, of the period of psychiatric study to discover what the individual aspects of the problem are for this particular person and to evaluate the severity of the addiction and the possibilities for reconstruction of the personality in his case.

In previous papers I¹ have attempted to assay these factors. In general one may expect to find a parental background characterized by inconsistency and lack of unanimity of parental discipline, resulting in conflicting, unstable identifications in the son. One parent, usually the mother, has always been overprotective and over-indulgent, shielding the son from the father's severity; the father has usually been inconsistently severe and indulgent, with considerable lack of real affection expressed and many clashes with the mother over discipline of the son. Such overindulgence combined with later sterner expectations and demands is, of course, more likely to occur in families of the well-to-do or wealthy class, from which the patients comprising this study are drawn. Innumerable personality shadings and accents are possible from a son's reaction to such parental management, but one regular result seems to be the fostering of excessive passive demands and expectations in the son—such passive, childish, feminine wishes being in marked conflict with masculine strivings inculcated by the father and by the cultural ideology absorbed from schooling and from contacts with other males. Excessive drinking supplies a compromise solution to both aspects of this conflict. It affords implicit gratification of passive oral wishes, and, at the same time, through the distorted standards of masculinity of late adolescence, provides the illusion of being masculine through his trying to be a hard-drinking he-man who can "hell around" with the boys. The same distorted conception of masculinity leads such boys into early heterosexual promiscuity in spite of the varying degrees of impotence caused by their conflict. I have labeled "essential alcoholics" those patients in whom one can discover plainly the evidences of oral fixation and passive, feminine wishes conflicting with masculine strivings, solved on contact with alcohol during adolescence by excessive drinking, with inability to carry on any sustained effort in school or in a job. They are

called "psychopaths" and are not even accepted for treatment by some therapists; and indeed their prognosis is bad, for a therapist has great difficulty in offering them a reality of sobriety and achievement which compares in satisfaction with their irresponsible dependent state. Treatment of such cases seldom lasts long anyway, since, becoming dismayed at the long road they must travel, they quit, on one pretext or another, or talk their relatives into believing that they are being badly handled or that they are now "cured." One finds that their main goal all along had been to attain through psychoanalysis a magically omnipotent state with ability to continue to drink, to have all the pleasures of drinking with none of its unpleasant after-effects.

A second more hopeful group may be called "reactive alcoholics." They are differentiated from the essential alcoholics by the facts of the history as much as by their attitude toward treatment. In nearly every case there is a discoverable precipitating event which initiated the severe drinking. Often their drinking is periodic, the sprees being reactions to reality stress. They have achieved more, have exhibited the capacity to carry through a sustained effort in schooling or in jobs, and their attitude toward treatment is more sincere. If their relatives do not interfere and interrupt the treatment prematurely, the outlook for them is good, unless their drinking has done too much damage to their reality situations that cannot be undone.

A third group might be called "symptomatic alcoholics." With these patients the drinking is only incidental, not the major symptom. There are other prominent neurotic or psychotic symptoms or even an organic illness. The diagnosis and prognosis of these patients depend on the main psychopathologic condition found.

TREATMENT

Combined institutional treatment and psychoanalysis is the treatment of choice in most cases of intelligent addicts to alcohol who sincerely want help. To say that institutional treatment is based on psychoanalytic principles means only that the activities of the patient and the attitudes of the doctors and therapists are "prescribed" on the basis of the discerned unconscious needs of the patient. Outlets for aggressive drives are prescribed and provided, anxiety is made endurable during periods of distress, and praise and affection are given at appropriate times. In other words the staff and nurses become wise, fair and moderately indulgent but consistently firm parents during the period of sanatorium care. Practically, this is carried out by having a psychiatrist other than the analyst take charge of the patient's privileges and regimen, with this psychiatrist and the analyst acting as checks on each other in relation to the patient's progress in analysis and his daily behavior. Detailed order sheets indicating attitudes to be assumed are prepared for the nurses and therapists, and these are frequently revised to meet new problems with the patient. When the patient has graduated from complete restriction to almost complete freedom with regard to privileges to come and go and has demonstrated his ability to handle the freedom given him, he may move out of the sanatorium and continue his analysis while living in an environment which is unsupervised.

Psychoanalytic treatment, directed at the searching out and working through of unconscious conflicts, with considerable reeducation involved, offers no magical or

1. Knight, R. P.: *The Psychodynamics of Chronic Alcoholism*, J. Nerv. & Ment. Dis. 86: 538 (Nov.) 1937; *The Dynamics and Treatment of Chronic Alcohol Addiction*, Bull. Menninger Clinic, September 1937, vol. 1, No. 7.

miraculous therapy. It depends always on the patient's motive power to go ahead. This motive power may be strengthened by wise handling, by being reinforced with a desire to please the analyst or by the better perspective and more attainable normality glimpsed through the psychoanalytic work, but fundamentally one can help the patient only so far as he continues to want and seek help in working out his conflicts.

Much of the content of psychoanalytic treatment is similar to that of other types of therapy in which the therapist strives through reeducation and interpretation of personality reactions to bring the patient to a better life adjustment. The chief difference lies in the attempt in psychoanalysis to follow the transference reactions and to choose the optimal time for the interpretations and reeducation in relation to the transference situation. In many descriptions of psychiatric treatment one gets the impression that the interpersonal relationship of patient and psychiatrist is almost completely ignored—except as the valuable leverage of the patient's confidence and trust and desire to please may be recognized. It is much more important for the psychiatrist to be able to perceive the evidences of distrust, of hostility, of need for affection and so on as they are portrayed in the nuances of the patient's speech and behavior. Interpretations and questions of the analyst are based on the perception of these transference manifestations, and the whole course of the interpretative content is based on and timed by such observations by the analyst. This, it seems to me, is the common sense as well as the chief distinguishing characteristic of psychoanalytic treatment.

RESULTS

One can work out the most rational understanding type of treatment and sanatorium management possible and still have it go on the rocks and be futile. This is especially true in attempting to deal with alcoholic addicts. There are two main rocks on which the treatment is shipwrecked: first, the flagging desire for help on the part of the patient, owing to his mounting resentment at the lack of satisfaction of all his childish demands; and, second, the interference of the relatives. Because alcoholic addicts have so many demands for gratifications and for having their own way, they have usually developed "winning ways" and various devices for getting their relatives to accede to their wishes. This interaction of parental inconsistency and patient's demands has become the very warp and woof of the alcoholic addict's interpersonal relationships. So it is that the alcoholic addict can again, when he becomes displeased with his treatment, persuade his parents or wife to rescue him from his unpleasantness or can provoke them, through his behavior, to refuse to spend any more money on him. The relatives want to believe what the alcoholic patient protests to them—that he has now seen the error of his ways, even though they may have been disillusioned on that score many times before. One can sometimes circumvent this by prophesying such a situation at the outset and by educating relatives to understand what is going on, but many times they will pay only lip service to these pronouncements and be taken in again by the promises of the patient.

A condensed summary of the results of attempted treatment of this series of twenty patients follows:

1. An oil promoter aged 32, who had scarcely drawn a sober breath for fifteen years, was brought drunk to the sanatorium against his will. He stayed for one month and had thirty daily

conferences of an hour each. He gained considerable insight and remained sober and achieved much for six months after he departed. He then relapsed badly.

2. A reactive alcoholic addict aged 29 was consulted as an outpatient during one of his sprees. He was seen ten times during and following the spree and made a good readjustment. When last heard of two years later he was doing well.

3. A reactive alcoholic addict aged 36 was brought in drunk by his irate, unreasonable father, and was seen twenty times during and subsequent to his sanatorium residence. His father took him out after a week, but the patient sought further consultations and made a good readjustment, which survived his father's death. He was doing well when last heard of a year after the treatment.

4. An essential alcoholic addict aged 35 was brought in drunk by his indulgent father and removed after ten days, against advice. He was seen ten times with no results and continued to drink.

5. A physician aged 34 came sober and voluntarily after he had beaten up his wife while drunk and she had left him. He was an outpatient, was seen six times in consultation, gained some insight and planned to have psychoanalytic treatment when he could arrange it. Four months later he was still refraining from drinking, had gotten his wife back, and was pointing toward the beginning of psychoanalysis.

6. A Jewish essential alcoholic addict aged 38 was seen for twenty analytic hours during the absence of his regular analyst. After some 200 hours with the other analyst, during the latter part of which he was making a fair adjustment as an outpatient, he provoked his relatives into removing him to another sanatorium, where he has now been for eight months, without privileges.

7. An attorney aged 46, a symptomatic alcoholic addict, who had lost one eye in an accident, never became very accessible in sixteen hours of psychotherapy but did no drinking during several weeks of complete privileges. He was removed by the relatives, relapsed in three months and was placed in another sanatorium.

8. An essential alcoholic addict aged 30 caused no trouble during two months of sanatorium residence but was never quite "sold" on the need for psychoanalysis. He was seen in two interviews and decided against psychoanalysis. He persuaded his father to remove him and there has been no follow-up report on him.

9. A capable newspaper man aged 34 became a voluntary patient after he became unable to do his work without heavy drinking, the situation being complicated by the loss of his little son in an accident. He was seen in twenty analytic hours and then referred to another analyst in a city where he could get a job. He is steadily improving, even though his wife deserted him when certain expected benefaction failed to materialize.

10. A divorced man aged 34, who had quit drinking two years before and who had made a serious suicidal attempt prior to that, came for psychoanalysis because of lack of ambition and inability to concentrate. There was a complex neurotic picture with much acting out which seemed to be equivalent to his former alcoholic sprees. He had forty-five psychoanalytic hours as an outpatient, during which he secured a job in another city and then left treatment. He worked hard, did well, and on the day he was promoted to a more responsible position died of an attack of coronary thrombosis.

11. An essential alcoholic addict aged 32, divorced, was brought in drunk, refused to cooperate during the first two months, and then began psychoanalysis. During 160 hours of analysis he was in and out of the sanatorium several times because of drinking and never gave up the hope of being able to drink like a gentleman. When it was finally insisted that he remain in the institution long enough to make some progress in his analysis before trying outpatient status again he balked and got himself released by habeas corpus action, which was not contested. He has continued to drink heavily.

12. An essential alcoholic addict aged 40, who had been declared incompetent and was brought to the sanatorium drunk by two deputy sheriffs, refused psychoanalysis for two months

and then began treatment. During 240 hours of analysis he improved greatly in his behavior and made a good adjustment as an outpatient. However, he continued to refuse to discuss his extremely maladjusted sex life and finally quit treatment. A few weeks later he had a severe spree complicated by an epileptic attack with severe head injuries and ensuing pneumonia. He recovered from this and was placed on a farm by his relatives, where he is now doing fairly well.

13. A playboy son aged 32 of a severe, eccentric millionaire father and a deceased mother who was schizophrenic the last fifteen years of her life remained in psychoanalysis for sixty-five hours with no drinking on full privileges, then easily persuaded his father to spend no more money on treatment. Six months later he was still doing no drinking.

14. A boy aged 27 with esthetic temperament was being forced by his father into the banking business and the boy reacted by drinking heavily. His mother had been a heavy drinker for many years. After the boy had made considerable progress in ninety-five hours of analysis and I was away on vacation his father announced to him that he must now shift for himself—no more treatment, no more financial help. He reacted with severe drinking and his wife left him. The patient was well on the way to recovery when the father interfered.

15. A reactive alcoholic addict aged 32, a capable mining engineer, entered the sanatorium drunk but cooperated well and made an excellent adjustment as an outpatient during the latter part of 157 hours of analysis. An attempt to try himself out at drinking again developed into a severe debauch, from which he was extricated without institutionalization again. He then decided to strike out for himself in the mining game in Bolivia and for two years has done exceptionally well, doing no drinking.

16. A severe essential alcoholic addict aged 28, and unmarried, remained in a stormy analysis for more than 300 hours, quitting when I left on a summer vacation. He has done some drinking in the eight months since but has stuck close to his new job and has gotten into no trouble.

17. A reactive alcoholic addict aged 30 with marked schizoid personality traits stopped analysis after 470 hours, having made a moderately good adjustment. The death of his father during analysis and the continued heavy drinking of his mother, together with his being surpassed in the family business by his rival younger brother during the patient's absence, complicated an already difficult analysis. He left convinced he must remain a teetotaler and hopes to return for more analysis later when drinking is not a part of the picture.

18. A reactive alcoholic addict aged 28 made a good outpatient adjustment after several months of combined sanatorium care and psychoanalysis. The family physician persuaded his father to stop the analysis after 160 hours and the patient has since made a good adjustment.

19. A reactive alcoholic addict aged 40 was seen in consultation four times. His severe drinking was precipitated by the wild antics of his wife after he had made a fortune in wheat. She divorced him and refused to let him see the children. He stopped drinking, took his children and their friends and his ex-wife on a trip to New York, was reconciled to his wife and remarried her.

20. A lawyer aged 30, an essential alcoholic addict, has been in analysis only twenty-five hours at this time but offers a good prognosis for recovery.

SUMMARY

This report is based on personal experience with twenty male alcoholic addicts, with whom I have spent a total of about 2,000 hours. Eight of these were not in psychoanalysis and three of these eight were not in the institution. Consultation hours varied in number from two to thirty. Two patients were unchanged, two relapsed after periods of three months and six months respectively, and four remained improved when last heard from but have probably relapsed. Of the remaining twelve who were treated psychoanalytically, one

was a former alcoholic addict who had stopped drinking two years before of his own accord and who was not in the sanatorium. The other eleven received combined sanatorium care and psychoanalytic treatment, the latter lasting from sixty-five hours to 470 hours. Two are still in analysis, one with me and the other with another analyst. The treatment of four patients was stopped by the relatives, one remaining slightly improved, one relapsing badly in reaction to the interference and two remaining moderately improved after some months. The other five patients stopped their own treatment for various reasons. Of these one was unimproved, three were moderately improved and one much improved.

I have tried to summarize the evaluation and classification of chronic alcoholic addicts and to indicate the rationale of combined sanatorium treatment and psychoanalysis. The difficulties in carrying on this plan of treatment long enough to effect permanent changes in the patient are enormous, not only because of the lack of a powerful enough urge to recover in the patient but also because of interference by the relatives. It has been conclusively proved by the experience of every therapist of persons addicted to alcohol that no individual who has for any considerable time used excessive drinking as a regressive method of avoiding facing his problems can ever hope to learn to drink socially. Sanatorium care to control his drinking for a few months and to provide a rational program of activities and outlets to meet his particular unconscious needs, combined with psychoanalysis which continues for several months after he has left the sanatorium, seems to be the most rational plan of treatment. Such a program should, depending on the severity of the case, last from eighteen months to three or four years.

ABSTRACT OF DISCUSSION

DR. F. G. EBAUGH, Denver: Alcohol and man present a wide variety of equations, most of which in our present state of ignorance seem insoluble. It may be wise to consider this from three points of view: 1. The impersonal or somatic point of view. Time does not permit discussion of the physiologic and morbid aspects of alcoholism, although recent advances in respect to the avitaminoses has led to a clearer understanding of some of the somatic residuals encountered in alcoholism. 2. The personal or point of view of the personality. I am in accord with Dr. Knight when he states that alcoholism is a symptom of some type of fundamental underlying personality disorder and that remedial measures to be effective must be directed at causal factors. 3. The interpersonal aspect, namely that of appreciation of the relationship of the patient to his environment. Sociologically, alcohol presents a tremendous problem. In the United States there has not been an adequate study, from a psychiatric point of view, of facilities and methods in use for the care of the chronic alcoholic addict. Fleming's review of the problem in England and on the continent reveals a marked disparity in methods of attack and attitudes of state, law and medicine. There is a need for a critical psychiatric and sociologic study of the alcohol problem in this country. I have utilized a diagnostic scheme somewhat varied from that suggested by Dr. Knight. I have divided those alcoholic addicts whom I have treated into five principal classes. But before this it may be wise to define what is meant by an abnormal drinker. Strecker's statement that drinking becomes abnormal when one drinks to excess in solitude and to escape reality is valuable. By situational alcoholism I mean those who are not overt, neurotic or psychotic and those who have graduated from the socially acceptable cocktail to abnormal drinking as a result of stress or strain environmentally. In my second group, alcoholism in relation to a true neurosis is self explanatory. Alcoholism simplex is a much more complex type, in which I believe the patient presents addiction to alcohol as an only symptom which

in itself may be a symptom of a deep-seated neurosis. This type of patient presents evidence of some type of psychosexual arrest. This may be similar to Dr. Knight's essential alcoholic. In the fourth group are the psychopathic personalities. In the fifth group, alcoholism is associated with a major psychosis, the defective disorders, schizophrenia and the organic reaction types. Treatment is most difficult. In addition to the two points stressed by Dr. Knight, one should not forget the financial factor, that of the need for adequate hospital study, which is rarely possible in most of the cases.

DR. KARL MENNINGER, Topeka, Kan.: In my earlier years in psychiatry I looked on alcohol addiction as a bad habit and a little later as a neurotic manifestation, one which was peculiarly annoying to the relatives and self destructive to the individual but one which ought surely to be accessible to various types of psychotherapy. Now I regard it as near a psychosis. I dare say some of my patients subsequently fall into the hands of other psychiatrists and I am sure that the patients of other psychiatrists come to me because the characteristic thing about the psychiatric picture of addiction to alcohol is that the patients have fluctuating periods of anxiety between which they feel relatively comfortable. When they have acute anxiety they drink and then they are not accessible to treatment; when they cease to have anxiety they do not want treatment, and that makes alcoholism an extremely difficult problem. I think that addiction to alcohol is more serious than any neurosis and should be thought of along with the psychoses. I think that the prognosis in schizophrenia is better than the prognosis in alcoholism. I would be inclined, if one of my young relatives had to have either schizophrenia or addiction to alcohol, to believe that his chances for getting back into a normal life would be greater if he had schizophrenia. If one treats alcoholic addicts only by letting them get over an acute attack and waiting until they promise not to drink any more, one can easily believe that what I have said is exaggerated. I used to think that too until I became increasingly careful with my follow-up system. Many alcoholic addicts have such strongly fraudulent characters that their wish to deceive the doctor is only a part of their wish to deceive everybody and to obtain relief from their anxiety in the way which they have found is the cheapest and most available. Dr. Knight's paper represents work that he has been doing for a number of years. It does not make any claims for extraordinarily good therapeutic results. My results are not very encouraging, any more than the treatment of schizophrenia is particularly encouraging. Some patients get well if one spends enough time with them, but the temptation is to think they are well simply because they have left with good promises. I agree with Dr. Ebaugh; we should make a concerted and persistent effort to be as scientific as possible in our investigation of what alcoholic addiction really is as a psychiatric syndrome and how it can be treated effectively.

DR. EDWARD E. MAYER, Pittsburgh: The reality situation of the privileged is slightly different from that of persons who are not protected by family and friends, and it is in respect to the latter class that I would like to say a word in respect to treatment. At a clinic that is municipally controlled and has one of my associates daily in attendance at the morals court, a large number of alcoholic addicts is examined. Those who he believes should have any psychoanalytic interpretation are given an appointment at the clinic. It is not a conscious reality that the alcoholic addict is evading or avoiding. Or put it this way: there are many realities in any group situation involving a particular individual. It is the interpretation of them that is important. Of course Dr. Knight recognizes this, otherwise he would not be a psychoanalyst. I wonder whether we are not too glib in talking of the reality situation of our patients or at any rate using it in a definition as does Dr. Strecker, who was quoted by Dr. Ebaugh. The dynamic problems do not permit me, at any rate, to claim for any one static reality situation such importance that it is differential. The chronic alcoholic addicts in their maladjustments that are brought to the morals court I find can best be approached and only approached by a modified psychoanalytic technic. I have been surprised how easy it is to give and how eager most of these patients are to obtain an understanding of themselves. So many

of them are with female dominance in the picture or impotent or have homosexual tendencies that the approach is not difficult. And the results have been fairly satisfactory—more so than in the class that Dr. Knight discussed, in which I have only a long record of disappointments. Dr. Knight, more skilled in psychoanalytic technic, can get better results, as his paper indicates, than the average social psychiatrist. His effort and his results deserve commendation.

DR. HERMAN S. MAJOR, Kansas City, Mo.: The method of treatment of alcoholic addiction in the clinic with which I am affiliated differs somewhat from the treatment presented by Dr. Knight in that we give patients liquor for a period of two or three days if they are drinking when they come in. We recognize that alcohol is not only a poison but a narcotic and that alcoholism is a disease and not a habit. There are five things that we attempt to do with our patients. We eliminate the poison from the system, we remove the desire for liquor, and we build up the patients' nervous systems and build them up physically, and then we attempt to change their psychologic outlook in that we endeavor to impress on them the fact that it is not the taint that does the damage but it is the person; therefore, regardless of what other people may do, they must adopt the psychologic view that as far as they are concerned they are too smart and they have too much sense to take poison and a narcotic deliberately into their systems. We do not restrain our patients and we refuse to accept restraint cases. Our patients are permitted to go out without being accompanied by an attendant forty-eight hours after they have taken their last drink of liquor. They are permitted to go out the first day for one hour in the forenoon and one hour in the afternoon, the next day for two hours in the forenoon and two hours in the afternoon, and following that they can take their medicine with them and go to a picture show or elsewhere without supervision. We have only one patient out of every 500 who betrays our confidence by getting something to drink while he is on the outside. We do not think that it is fair to punish 499 others just to catch one fellow who does not want to do the right thing. We lecture to our patients on the effects of alcoholism on the nervous system. We have had experience with several thousand cases, and out of every hundred patients who remain with us for four weeks with the follow-up treatment at home and subsequent check-up, eighty remain abstinent. Of the fifteen or twenty who resort to drinking we find that they do so not because they have a desire for drinking but because they want to be good fellows, and a good many of them return and take the treatment a second time. They have learned their mistake and most of them make good. I think the psychologic treatment after one has had the alcohol eliminated from the patient is an important measure.

DR. ROBERT P. KNIGHT, Topeka, Kan.: Dr. Ebaugh's classification of drinking coincides closely with mine. His "situational" group is practically equivalent to the "reactive" group of which I spoke, the "simplex" group is equivalent to my "essential" group, and the symptomatic cases, which comprised my third division, include his psychopaths, psychotics and neurotics. I agree with him that a sociologic study is necessary, and I would call attention to a good suggestion made by newspaper columnist Westbrook Pegler to the effect that the liquor industry be taxed and the proceeds used to pay for the treatment of those who overuse their products. This is an excellent idea. With Dr. Menninger's remarks I agree. With regard to Dr. Mayer's comments, I do not believe that we need to be vague about what "reality" is. If an alcoholic addict has a dominating wife, if he has children and cannot endure their being taken care of in the way that he wants to be taken care of and cannot admit, if his father has recently died and he was always dependent on his father for financial support, these are factors in his reality. With regard to Dr. Mayer's point about impotence sustaining the alcoholism, I would look on both the impotence and the alcoholism as symptoms. The impotence often precedes the alcoholism, and while it may be true that the one now sustains the other, one may not list these as cause and effect. With regard to Dr. Major's remarks, persuasion and lecturing of alcoholic addicts has been going on for many years. The relatives and the preacher try it long before they consult

the psychiatrist. The alcoholic addict knows that he is taking a poison into his system. If one uses this approach to try to persuade him not to drink, one is neglecting entirely the point that many alcoholic addicts drink because they unconsciously want to destroy themselves from strong feelings of guilt and need for self punishment. With regard to Dr. Major's remarks about eighty alcoholic addicts out of every hundred treated remaining abstinent, congratulations!

CEREBROCRANIAL INJURIES

DETAILED STUDY OF 1,433 CASES

GEORGE W. SWIFT, M.D.

AND

S. N. BERENS, M.D.

SEATTLE

The past quarter of a century has witnessed an increase in the number of cerebrocranial injuries in both the larger centers and the rural districts throughout the land. What was at the beginning of this century a rare surgical problem has become one of frequent occurrence in hospital practice. The American Medical Association and the American College of Surgeons have both given it wide publicity, and scientific statistical exhibits on this subject have been displayed at their annual meetings; state societies and regional meetings have featured papers on it; journals have published excellent articles covering all phases of the subject;

TABLE 1.—Mortality Study in Seattle Over a Period of Eighteen Years

| Period | No. of Cases | Death Within 3 Hr. | Death Within 24 Hr. | Death After 24 Hr. | Total Mortality |
|---|--------------|--------------------|---------------------|--------------------|-----------------|
| 1919-1924..... 60 months | 178 | .. | .. | .. | 60.7% |
| March 1931-December 1932..... 21 months | 175 | .. | .. | .. | 23.3% |
| October 1934-March 1935..... 6 months | 214 | .. | .. | .. | 19.1% |
| October 1936-March 1937..... 6 months | 145 | .. | 10 66% | 5 33% | 15 10.3% |
| October 1937-December 1937..... 3 months | 107 | 4 30% | 10 77% | 3 23% | 13 12.1% |

research workers have contributed their share, and hospitals have furnished equipment and supplies desired by surgeons in the treatment of these patients. The result of all these combined efforts has been to decrease the mortality; nevertheless the incidence has rapidly increased (table 1).

Recent articles have shown remarkable agreement in the basic factors involved in handling any serious cerebrocranial injury.¹ The reports of series studied in various centers have shown a tendency toward uniformity in treatment and results obtained. A striking fact in these reports is that with each series from large centers the percentage of operative intervention has shown a gradual decline; a standardized technic for the emergency treatment has been adopted. In this emergency treatment great importance is attached to maintenance of water balance; measures to relieve or prevent shock are considered as imperative first aid essentials; delayed roentgenography is advisable except in com-

pound comminuted fractures, and, finally, patients are given more or less standardized treatment for twenty-four hours. Of the patients who have survived the acute stage, those with mild injuries are given simple rest and those with severe injuries are transferred to the care of more experienced surgeons and nurses for expert post-traumatic attention.

From time to time we have made reports on our results obtained during the past fifteen years.² We have had demonstrations at various county, state and regional medical meetings. At Harborview (King County Hospital)³ we have adopted a uniform or standard treatment based on our observation of results obtained. This has been changed from time to time as we have become convinced that certain forms of treatment give better results. The occasional spinal puncture, for instance, has in our service become established as routine on all patients who survive the first twenty-four hour period. Spinal drainage repeated daily on all patients who show blood in the first puncture is continued until the fluid returns clear. Encephalography in all patients having a persistent severe headache with a spinal fluid manometric measurement above 6 mm. of mercury in the prone position is considered advisable for both diagnostic (blood clot) and therapeutic purposes. Under this routine our morbidity has been lessened and our mortality has been decreased almost 50 per cent (table 2).

The first treatment has been directed toward the control of shock. Absolutely no other objective is considered. This may require only a few hours or may take a longer period. The treatment aims to keep the water volume in the vascular system, carry oxygen to the brain cells, prevent accumulation of fluid in the interstitial spaces and support the heart.

Our routine regarding spinal punctures is as follows: Every patient who has shown definite signs of concussion or skull fracture or concussion and skull fracture combined is given a spinal puncture after the first twenty-four hours and before leaving the hospital. Certain patients may have spinal punctures before this period. In mild cases spinal punctures are usually performed about the twelfth hour. In serious cases, spinal punctures should be delayed until after the small veins have thrombosed or the arteries have contracted. This will prevent a recurrence of hemorrhage from these vessels. Since we have adopted the rule, we have been able to segregate our patients and hold many in the hospital who might otherwise have been permitted to go home or be transferred to another hospital. The presence of bloody cerebrospinal fluid in our experience immediately stamps the case as one with at least a mortality rating of 45 per cent. We have not felt that withdrawal of 5 or 10 cc. of fluid in the prone position adds any risk to the patient. We have not seen bad effects in a single case. Many patients have been greatly benefited. Spinal punctures were done on 121 in one series of 145 patients and on fifty in a series of 169 patients. In the first series of 121 cases bloody spinal fluid was found in forty-one cases, while it was

3. King County Hospital is commonly known as Harborview Hospital.

found in twenty-five in the series of fifty cases. A total of 171 patients, or 54 per cent, of the total series had spinal punctures and of these sixty-six, or 21 per cent, of the total series had bloody spinal fluid.

Roentgenograms demonstrated fractures in fifteen, or 4 per cent, of the series. However, this is not so significant because none were taken until after the first forty-eight hours and, if the spinal fluid was free from blood and the patient recovered completely from shock, no roentgenograms were taken. It is not always possible to obtain films for one or another reason.

The question arose as to how the figures compared with the results in other hospitals. First we studied our series of 145 cases during a six months service at Harborview. Then we studied 169 cases during the following six months in the next service where the same treatment, except for routine spinal drainage, was used. We sent a questionnaire to all the standardized hospitals in the state of Washington, asking for a report on all their hospitalized cerebrocranial injuries treated during the same annual period. The purpose of the survey was to determine certain fundamental facts which we believe to be true. The Northwest has had a very intensive campaign for the past ten years directed toward a better understanding of the principles on which modern treatment of severe cerebrocranial injuries is based. Such national leaders as Fay,⁴ Mock,⁵ Adson,⁶ Craig⁷ and Ochsner⁸ have presented the subject before county and regional medical meetings. Practical demonstrations, tabulations of results, exhibits of scientific specimens, illustrations of various lesions and physiologic reactions of water balance have been presented at many meetings throughout the state of Washington. Interns who have had an intensive training have located in many smaller centers and have spread the knowledge gained at the large hospitals in the larger cities. It was our belief that if the fundamental principles were sound the state

(2) the reports from the state board of health were essentially identical, we knew that the mortality figures were accurate. We did find a lower mortality in our lists than in the official list because of the fact that in a certain percentage of fatal cases the patient never reaches the hospital but is taken directly to the morgue. These form a considerable number of the total and of course increase the total mortality for the city. Some hospitals do not consider a patient who dies within an hour or so

TABLE 3.—Mortality Study: Dr. Temple Fay, Philadelphia

| | No. of Cases | Death Within 3 Hr. | Death After 3 Hr. | Total Deaths |

| Totals..... | 655 | 27 4.1% | 90 13.7% | 117 17.8% |

after admission as a hospital patient and make no record. Several such instances were found in our check-up.

In order to compare our records with others, we obtained a detailed report (table 3) from Dr. Temple Fay of the Temple University Hospital of Temple University School of Medicine, Philadelphia, of the results he obtained in his clinic. Fay has included in his series all the patients admitted to the Neurosurgical Department, even those who died within the period of an hour. In his report 4.1 per cent died within three hours. In our series 7 per cent died within twenty-four hours. Fay's final mortality is based on his entire series of head injuries. Perhaps his last hundred cases would show a much lower mortality. Also I have tabulated the results of a series of cases (table 4) by Dr. Harry E. Mock of St. Luke's Hospital and Northwestern University Medical School, Chicago. This includes a series of private patients and another series of proved skull fractures submitted to him by eighty surgeons throughout the country, showing the end results. Both Fay's and Mock's final mortality include all their cases reported during the last few years. Temple University Hospital is situated in the center of Philadelphia and undoubtedly receives many emergency cases presenting severe injuries. This would tend to increase the mortality in Fay's tabulations. St. Luke's Hospital is located in the center of Chicago, but according to Mock's tabulations 10 per cent of his patients died from concussion only while 5.4 per cent of Fay's patients died from concussion only. Possibly this accounts for the difference in their mortality rate. Harborview Hospital received all emergency cases until 1936, and our mortality was 19.1 per cent. Since then emergency cases are taken to the nearest hospital. This undoubtedly accounts for the rapid decrease in the mortality of Harborview Hospital.

In the series of 314 cases at Harborview there were thirty-seven deaths. Of these twenty-two, or 59.4 per cent, of the deaths occurred within twenty-four hours. Another four deaths occurred within the second twenty-four hour period, making 70 per cent of the total number of deaths within forty-eight hours. These deaths were not always due to the head injury alone. In some instances severe chest and abdominal injuries may have

TABLE 2.—Morbidity Study: Comparative Period of Hospitalization

of Washington should have a valuable report to submit in the care and treatment of cerebrocranial injuries.

In order to check the reports from an impartial angle, all deaths reported to the state of Washington from the cities of Seattle and Yakima were reviewed. As the two series (1) the questionnaires from the hospitals and

been associated, but we included in this series all severe head injuries treated by the department of neurosurgery.

In table 5 we have made a more detailed study. We have used as a control (series A) 145 patients treated at Harborview in our service over a period of six months. One hundred and sixty-nine patients (series B) were treated the following six months in two different services. This totals 314 patients at Harborview

TABLE 4.—Mortality Study: Dr. Harry E. Mock, Chicago

| | No. of Cases | Mortality |
|---|--------------|-----------|
| Concussion only..... | 550 | 10.0% |
| Concussion and skull fracture..... | 275 | 17.8% |
| Total..... | 825 | 12.5% |
| Cases reported to Dr. Mock by 80 surgeons | | |
| Proved skull fracture..... | 875 | 26% |

| Deaths within 24 hours..... | | 45% |

for a period of one year. During this time the other hospitals in Seattle treated 222 cases. We tabulated the cases treated in hospitals in the state of Washington with 100 or more cases, those with from twenty to 100 and those with less than twenty cases. We then compared the results in 1,433 cases treated in all the hospitals in Washington.

We studied the total number of deaths in the hospitals with more than 100 cases, with twenty to 100 cases and with less than twenty cases and compared the number of deaths which occurred between twenty-four and forty-eight hours and after forty-eight hours (table 7). In this study it is interesting to note that 55 per cent of the deaths occurred within the first twenty-four hours

and in an additional 13 per cent death occurred within the next twenty-four hours; in almost 70 per cent death occurred within the first forty-eight hours.

Finally we made a study of the morbidity in Harborview (series A and B), other hospitals in Seattle, and all the hospitals in the state of Washington (table 6). It is interesting to note that in series A 73 per cent of the patients remained in the hospital less than a week, 19 per cent remained less than two weeks and 6.9 per cent remained more than two weeks. In series B 8.3 per cent remained in the hospital more than two weeks. The only difference between series A and series B was the spinal drainage. We believe that this accounts for the lower morbidity.

COMMENT

From these studies certain fundamental facts are apparent:

Early Shock.—The first important fact is that every patient brought to the hospital with a severe head injury should be given routine treatment for shock and then watched for signs of hemorrhage. Fay has shown in many articles, and his report again conclusively demonstrates, the value of water balance in the treatment of shock in head injuries. It is as important to prevent secondary shock as to control primary shock. This can be done only through sustaining the water balance.

Hemorrhage.—Most cases of hemorrhage can be controlled, but massive hemorrhages on the one hand and undiagnosed hemorrhages of the middle meninges on the other cause many of the deaths. The first cannot be controlled, but the second should be diagnosed and treated surgically. Petechial hemorrhages within the ventricular walls and brain stem cause death in cases of severe concussion. These again are beyond the reach of treatment. In Fay's series they caused 5.4 per cent of the deaths. Our series shows about the same proportion.

Morbidity.—Our tabulation shows that in the control series at Harborview the first and second series were almost identical; 73 to 77 per cent were hospitalized less than a week. This series includes (1) those patients who died within the first forty-eight hours, (2) those whose spinal puncture revealed no blood in the spinal fluid, (3) those who recovered promptly from shock and (4) those with no other serious injury. The study shows that this percentage decreases in the Seattle hospitals to 65 per cent and in the state hospitals to

67 per cent. In other words, under the assumption that the treatment is the same, except for a decrease in the number of spinal taps for diagnostic purposes, if the number of patients leaving the hospital is greater owing to the positive assurance of absence of severe injury obtained from taps (clear spinal fluid) the treatment is well worth while. In the next column—those remaining less than two weeks—it is found that all series show 17 per cent average, except the controls at Harborview, where the percentage is 19 per cent. Here the difference is in spinal drainage, and in the series in which drainage is routine for patients with bloody spinal fluid and a careful check on water balance is maintained, the percentage drops from 19 to 15. This should also

show in the lessened morbidity, the stay in the hospital being prolonged beyond the two weeks period: Harborview control 6.9 per cent; other services 8.3 per cent; average 7 per cent; Seattle hospitals 17 per cent; state hospitals 15 per cent. The conclusion must be that spinal drainage and water balance control lower the morbidity and decrease the hospital period.

Special Treatment.—The study gives a further suggestion regarding treatment. In the larger hospitals where more attention can be given both by the hospital personnel and by the surgeon specially trained to treat these patients, one finds a lower mortality and morbidity and better end results; the records are better kept and the combined results are better. In the smaller hospitals, again, these same factors are present. Usually one surgeon sees all the patients and he becomes expert in handling them. He equips himself to meet emergencies; he calls in outside help whenever he finds a serious factor developing. He uses the long distance telephone to secure expert consultation, and his records show a better result. In the larger private hospitals more individual surgeons treat a small number of

4. Every hospital should have at least one surgeon on its staff who makes a special study of this type of case and is available for consultation in regard to all serious complications.

5. Spinal puncture and spinal drainage, water balance control and constant care should be used in an effort to save lives, classify cases, prevent morbidity, and shorten hospitalization.

6. Records should be kept so that any subsequent study of the cases may be of some value.

902 Boren Avenue.

ABSTRACT OF DISCUSSION

DR. HARRY E. MOCK, Chicago: The Pacific Northwest, and especially the state of Washington, have become head-injury conscious. As a result, the high mortality from this type of trauma has been definitely lowered. My opinion has been that the statistical study of mortality rates for purposes of comparison should be based on some common measuring rod. One man's interpretation of the seriousness of a head injury may differ widely from another's. Thus, in comparing my mortality rate in 275 proved skull fractures with approximately 3,000 proved skull fractures collected from other sources, I have used the presence of a skull fracture as the common measuring rod. Since the presence of the fracture adds materially to the seriousness in the majority of cases, the mortality rate in proved skull fractures is bound to be higher than in a group including all head injuries, regardless of fractures. The serious head injury requires exactly the same meticulous management as does the skull fracture. Since from 50 to 60 per cent of the deaths from skull fracture occur in the first twenty-four hours, and since the majority of these cases occur outside the medical centers where neurosurgeons reside, it is evident that the emergency and early management of these cases falls largely to the general physicians and surgeons throughout the country. This will always be a social problem the solution of which is the responsibility of the rank and file of the profession as well as of the specialist. There is no routine treatment applicable in every cerebrocranial injury. The treatment adopted depends absolutely on the signs and symptoms of each individual case. In the more serious brain injuries these signs and symptoms, indicating increasing cerebral volume, increasing intracranial pressure and threatened medullary compression, develop and change rapidly in character during the first twenty-four hours. It is essential, therefore, that an hourly chart of the pulse, respiration, blood pressure and often the temperature be kept and frequently studied, that the attending surgeon practically live with such patients, if these changes are to be noted in time to institute the indicated life-saving procedures. Speaking in terms of skull fracture, the high mortality rate can be reduced. Many will be saved if heed is given to the authors' remarks concerning shock. Based solely on their signs and symptoms, dehydration will meet the situation in approximately 50 per cent of the cases. It should never be carried to the absurd point of overdehydration. Spinal puncture, definitely indicated in approximately 34 per cent of all skull fractures, is the greatest life-saving measure.

DR. GEORGE W. SWIFT, Seattle: Dr. Mock and I do not agree on what the measuring rod should be, but it does not matter how one arrives at statistics if one keeps reporting from time to time and uses the same measuring rod for his report. That is what I have tried to do and I am sure that is what Dr. Mock has done. In the end, if we tabulate our records, we all come within a few points. Dr. Temple Fay has practically the same mortality rate as we have as shown by his tabulation. Dr. Mock mentioned the incidence of operative intervention as being approximately 5 per cent in his series. It is lower in our series. Dr. Dandy, on the other hand, has higher incidences. We are all attempting to arrive at the same general end results in the method that each of us prefers to use. Dr. Dandy is one of America's most skilful neurosurgeons. In his hands, operative procedures are easy and undoubtedly save many lives. For the rank and file of surgeons in America to have his keenness of operative sense and operative ability is hardly possible. They must have other means at their command

TABLE 6.—Mortality Study

| Total Deaths | Within 24 Hr. | 24 to 48 Hr. | After 48 Hr. |
|--|------------------|-----------------|-----------------|
| Hospitals with 100+ cases (84 deaths)..... | 45 53.5% | 8 10% | 31 36.5% |
| Hospitals with 20-100 cases (94 deaths)..... | 53 56.4% | 15 16% | 26 27.6% |
| Hospitals with 20 cases or less (17 deaths)..... | 10 58.8% | 2 12% | 5 27.2% |
| Totals (195 deaths)..... | 108 55.4% | 25 13% | 62 31.6% |

patients; frequently there is no intern or the intern is too occupied with many other duties to give his undivided attention to the individual case; no routine has been established for the emergency treatment in all cases and the result is shown in the records: a greater morbidity and a higher mortality. A further factor which one must consider in this relation is that private hospitals receive patients with severe head injuries in emergencies. When identification has been completed and the shock symptoms have subsided, the indigent patients are transferred to the county hospitals. These are the poorly nourished, older and possibly diseased patients; facts which tend to increase the percentage at the county hospitals. Again in the county emergency hospitals after the identification has been completed and shock symptoms have subsided, many patients able to pay for private care are transferred to other hospitals. This tends to increase the percentage of the first week hospital period in the county hospitals and to increase the percentage of the lower hospital periods in the private hospital group. These conditions would suggest that the private hospitals should have much better results than the county or smaller hospitals, but the records do not substantiate this.

CONCLUSIONS

1. Periodic statistical studies should be made by each hospital caring for severe head injuries.
2. The average percentage established for the region by the county hospital should represent at least the lowest figure with which the hospital staff should be satisfied.
3. Special emergency routine care should be established and insisted on from any and all surgeons.

to reach the same end. In the hands of Dr. Fay, dehydration is the ideal treatment. Perhaps no man in America can handle a head injury case with such skill in the use of water balance. He uses dehydration for the same end result as does Dr. Dandy: the operative release of the encased fluid in the subdural and subarachnoid spaces. Here again the exercise of proper skill and judgment in the maintenance of water balance requires exceptional ability. We attempt to obtain the same results by spinal drainage. We feel that the average surgeon throughout the country had better rely on this very simple procedure rather than the more difficult surgical intervention and more technical water balance maintenance. In the end, what we all try to do is to prevent an accumulation of fluid, blood or spinal fluid within the cranial cavity to such a degree as to stop the normal function of the brain.

MEDICAL SUPERVISION OF BENZENE PLANT WORKERS

ADOLPH G. KAMMER, M.D.

NATHAN ISENBERG, B.Sc., Ch.E.

Chief of Examining Clinic and Chief Chemist, Coke Plant,
Respectively, Inland Steel Company

EAST CHICAGO, IND.

AND

MELVIN E. BERG

Technician, Saranac Laboratory

SARANAC LAKE, N. Y.

The current emphasis on preventive efforts in medical practice finds its counterpart in the rapidly progressing field of industrial medicine. The medical departments of mills and factories, at first concerned only with the repair of injuries caused by accidents, later devoted time to the diagnosis and treatment of disabling occupational diseases. The time is at hand when plant physicians must extend their interests beyond the walls of their offices and cooperate with engineers in the eradication of industrial disease at the points of its inception. The industrial physician's essential part in this program is one of constant supervision over the physical status of workers. When workers handle toxic substances, even though they are afforded theoretically perfect mechanical protection, the medical surveillance must be methodical and unrelenting. This rule holds for the supervision of benzene (benzol, C_6H_6) plant workers, who are usually considered to be free from the danger of chronic benzene poisoning.

At the time the work reported here was begun it was felt that a satisfactory supervision of such workers should include three procedures: (1) the periodic determination of the relative proportions of inorganic and organic sulfate in the urine of employees, as first suggested by Yant and his co-workers¹ and later advocated by Schrenk and his associates;² (2) complete hematologic studies of the workers, and (3) determination of the concentration of benzene in the air at various points in the workings.

The plant for which this study was made regularly employed about eighteen men, whose ages when first examined varied from 20 to 53 years and whose work exposure ranged from twelve months to fifteen consecutive years. The project was begun in August 1936, with complete physical, hematologic and urinary

examinations of each employee. Urine sulfates were determined as a part of this examination. Thereafter they were determined once each month, and the blood was examined about every six months. Determinations of the concentration of benzene in the air of the plant were made at irregular intervals and then chiefly for the purpose of checking the satisfactory operation of the ventilating equipment as well as the information gained by clinical methods.

URINE SULFATES

Preliminary Considerations and Studies.—The value of the inorganic-organic sulfate ratio in the urine as a factor indicating benzene absorption was first established by the workers headed by Yant¹ at the Pittsburgh station of the U. S. Bureau of Mines. It was shown by them that the absorption of even small amounts of benzene causes an increased proportion of the total sulfates of the urine to appear as organic salts. The explanation offered for this phenomenon was that the absorbed benzene is oxidized in the body to phenolic products, which are conjugated with sulfates by the liver and eliminated as such combinations by the kidneys. This explanation is well supported by previous work, quoted by Kahn and Goodridge.³ It was theorized that severe damage to the liver would interfere with this normal process of detoxification, and Smyth⁴ found that persistently high levels of inorganic urine sulfates obtained in animals subjected to toxic concentrations of carbon tetrachloride.

Yant's experiments, performed on dogs, showed that of the total sulfate of the urine from 10 to 15 per cent ordinarily is present in organic form and that the remaining 85 to 90 per cent occurs as inorganic salts. Animals exposed to 100 parts per million of benzene in air (the concentration generally accepted as being non-toxic for man) for eight hours showed a definite shift in favor of the organic component of the total urine sulfates. With increased concentrations of benzene in the air and greater exposure times the proportion of inorganic sulfates dropped rapidly and markedly. This characteristic reaction was found to precede changes in the blood by considerable periods, occasionally by many months. In a subsequent publication the same group² reported that the proportion of inorganic sulfate in the urine of healthy, unexposed men might occasionally drop to 81 per cent of the total sulfates eliminated.

A total of 106 specimens of urine from a like number of normal, unexposed workers were examined as controls to one phase or another of the present study. Five showed a value for inorganic sulfate in the range from 77.08 per cent (the lowest encountered among unexposed normal persons) to 80 per cent of the total sulfate. In all the remaining 101 specimens the inorganic fraction was greater than 80 per cent of the total sulfate.

Efforts at establishing a satisfactory technic showed that specimens of urine could be stored at 45 F. for at least two weeks without altering the sulfate ratio. A trial of the several methods described in standard textbooks⁵ for determining sulfates in urine showed that in the laboratory in which this work was to be done the

method of Folin⁶ was the most satisfactory from the standpoint of ease of performance and duplication of results. This also was the method used in the original work at the Bureau of Mines.¹

An attempt was made to determine the diagnostic specificity of a drop in percentage of inorganic urine sulfates. An arrangement was made with a local hospital whereby specimens of urine from patients with proved diagnoses could be examined. The specimens were stored in a refrigerator immediately on collection and were analyzed within a few days. An opportunity presented itself at the same time for studying the effect on urine sulfates of drugs containing benzene radicals in their chemical structure.

The urine of 108 hospital patients was examined. It developed that this portion of the study could not be satisfactorily controlled, and definite conclusions can therefore not be drawn. Two of the patients were being treated for acute rheumatic fever. The first of these was receiving 30 grains (2 Gm.) of sodium salicylate daily, and the second was receiving 60 grains (4 Gm.) daily of the same drug. The inorganic fraction of the total sulfate was 64.29 and 68.08 per cent, respectively. No specific condition was encountered which of itself, independently of medication, caused a significant shift in the sulfate ratio. Nonbenzene workers under treatment for syphilis and receiving one or two injections of neoarsphenamine or mapharsen weekly showed no decrease in inorganic sulfates below 80 per cent of total urine sulfate.

Studies on Benzene Plant Workers.—It was pointed out by Yant¹ that the elimination of benzene is greatest when its absorption is at its peak and that with the cessation of exposure elimination drops off progressively with the passage of time. In order to insure the obtaining of urine from workers during their periods of greatest exposure, appointments for their appearance at the clinical laboratory for the purpose of voiding specimens were carefully worked out. Each man reported during his shift and only after he had worked for three successive days. The specimens were stored in an electric refrigerator until they could be conveniently analyzed, usually from one to four days later. They were voided in the presence of a technician and analyzed by a chemist's assistant whose ordinary work it was to make quantitative chemical analyses in the coke plant a short distance away. Specimens were sent to him with only a number for identification.

As was previously stated, specimens were usually analyzed for each worker every month during the period of this study. The average number of men employed during the eighteen months covered was eighteen. A total of 240 sulfate determinations was made on single specimens of urine. The lowest value for inorganic sulfate revealed by these examinations was 66.34 per cent of the total sulfate. The inorganic fraction of the total sulfates ranged from this figure to 70 per cent in two instances, from 70 to 80 per cent in twenty-eight instances and above 80 per cent for the remaining 210 analyses. Readings below 80 per cent occurred thirty times for ten men.

HEMATOLOGIC STUDIES

Hamilton⁷ has stressed the importance of making complete blood counts for patients suspected of having

chronic benzene poisoning and has condemned the practice of expecting a so-called typical picture. She expressed the opinion that there may be destruction of any of the cellular components of the blood. That neutropenia commonly follows overdoses of benzene by alimentary or respiratory portals is well recognized. Duke⁸ reported experimental work showing that the platelet count may be reduced. Hayhurst and Neiswander⁹ reported a case in which, among other significant abnormalities, there was increased fragility of

the red blood corpuscles. Hurwitz and Drinker¹⁰ called attention to a possible impairment of prothrombin formation, and Hektoen¹¹ reported experiments showing that there is a decreased resistance to infection in animals receiving benzene by subcutaneous injections. An estimation of changes of the last two types was considered too difficult of achievement to be incorporated

in the work being reported here. Besides this, the work of Hurwitz and Drinker showed that circulating prothrombin is diminished only with the advent of severe poisoning. No cases of this type were encountered in the present study.

The following were determined for each worker at the time of his first examination, in August 1936, and thereafter approximately at six month intervals: erythrocytes, leukocytes and platelets per cubic millimeter; differential white blood cell count; hemoglobin percentage, and fragility of the erythrocytes. Single determinations of the bleeding time and clotting time were made for each man. The sedimentation rate and the Kahn reaction of the blood were determined, and a complete urinalysis was performed at the first visit as a part of the general examination made of all employees of the firm.

If one considers the lower limit of normal for the erythrocyte count to be 4,500,000 per cubic millimeter, there were twenty-six subnormal counts for fourteen men. The accompanying table summarizes these and indicates where possible the figures representing the inorganic fraction of the total urine sulfates, both for the day of each blood count and for the preceding month. No abnormal total or differential white cell counts were noted in the entire study, and no increase in the fragility of the red blood corpuscles was encountered. Bleeding and clotting times, of which there were single determinations made for each worker, were all normal. There were no instances of thrombopenia.

BENZENE CONCENTRATION IN PLANT AIR

Determinations of the benzene concentration in the air were made according to the method of Schrenk and his co-workers.¹² As previously noted, they were not made with any planned regularity, and they were used chiefly to estimate the efficiency of ventilation. Determinations were made at all places revealed by plant inspection and clinical data on workmen to be points of possible benzene exposure.

For the most part the clinical data did not coincide with the results of air analyses. The explanation for this appears in the original articles of Schrenk and Yant. Air analyses determine concentrations at particular times and do not necessarily reflect conditions prevailing over long periods, whereas changes in the urine sulfate do indicate the degree of benzene exposure and absorption for a given employee's entire work day. When an employee's job takes him to a number of stations within the plant it becomes difficult indeed to estimate his exact exposure from air analyses alone. The difference in time between the obtaining of clinical data and the making of air determinations made impossible an exact correlation between the two in this study.

The highest concentration of benzene in the air found at any time was 400 parts per million. This was found at the only point in the plant where benzene cannot be kept entirely enclosed. Two workers (1 and 6 in the table) were presumably equally exposed at this job. The first (1) rather persistently showed an inorganic sulfate percentage of less than 80 and a lowered red blood cell count. The second (6) had only one subnormal red cell count and always had a normal urine sulfate ratio.

COMMENT

The experimental work of Schrenk and his associates has introduced a specific test for benzene exposure among workmen. When the inorganic fraction of the total urine sulfates of such persons drops markedly below the experimentally established normal of 80 per cent, there can be no doubt that benzene is being absorbed and excreted. Values ranging from 65 per cent to 80 per cent, however, represent a doubtful zone and are not to be used as specific evidence of benzene exposure. One needs to weigh other important factors, viz. the history of suspicious symptoms and exposure, the blood picture and the results of complete physical examination, before establishing the diagnosis of the milder forms of benzene morbidity. In a regular supervision of benzene plant workers one sees values for inorganic sulfate in the range from 70 per cent to 80 per cent of the total urine sulfate rather commonly interspersed throughout series of higher readings. From observations made on the present group of workers it can be stated that such values are not cause for concern.

Mild anemias, usually transitory, occur rather commonly among benzene plant workers, just as they do among most industrial workers. There were twenty-six red blood cell counts below 4,500,000 per cubic millimeter among fourteen men. Worker 1 had four such counts, of which two were associated with a value for inorganic urine sulfates above 80 per cent and two with values within the doubtful zone just below that figure. This worker, however, had enough other instances of a slightly lowered value for inorganic urine sulfate to warrant attributing his mild anemia to benzene inhalation. He had no other symptoms, such as anorexia, loss of weight or weakness.

The remaining lowered red blood cell counts observed in this study occurred in association with normal values for the inorganic urine sulfate. The exact causes for the slight anemia could not be discovered. That it was probably not serious was indicated by the further observation that within individual series the counts fluctuated between normal and subnormal figures from time to time, that none of the men lost weight, that absenteeism was about the average for the payroll of the entire firm and that the men always stated that they felt well.

Worker 2 had been employed about a month at the time of his first examination and worked at a point known to be nonhazardous. He had the lowest red cell count discovered in this study. His urine sulfate values confirmed the belief that he was absorbing no benzene and he was advised to have an obvious focus of infection treated. Two months later his red cell count had returned to normal and he had lost no time from his regular work. This case illustrates the advisability of hematologic studies on applicants for jobs which entail a possible benzene exposure.

The determination of the benzene content in the air of a plant has no great value as a routine measure in the supervision of the workmen's health. Significant concentrations are immediately detectable by the sense of smell, and careful inspection of plant equipment reveals their sources. The discovery of such concentrations properly falls to production foremen and workers. The detection of the smallest concentrations can more easily and certainly be accomplished by systematic determinations of urine sulfates among all exposed employees.

12. Schrenk, H. H.; Pearce, S. J., and Yant, W. P.: A Microcolorimetric Method for the Determination of Benzene, U. S. Department of the Interior, Bureau of Mines, report 3287.

CONCLUSIONS

1. The periodic determination of the inorganic fraction of the total sulfate in the urine of workers is an entirely satisfactory form of medical supervision of employees exposed to a possible benzene hazard. In plants where benzene is kept in closed containers a monthly examination of this type is adequate.

2. In the supervision of the workmen's health, hematologic studies find their chief practical value in the preemployment examinations of applicants for work.

3. In a given case of any blood dyscrasia in a worker in a plant using benzene, that substance should not be incriminated as the causative factor without a complete study of the worker and his job. A determination of the urine sulfate is helpful only if the subject is still at work and subjected to his customary exposure.

3210 Watling Street.

ABSTRACT OF DISCUSSION

DR. PETER K. KNOEFEL, Louisville, Ky.: Benzene is changed in the body into phenolic substances, but since varying amounts of different phenols are formed and conjugated in different ways with sulfuric acid, with glycuronic acid, it may be seen how complex the quantitative aspect of the situation can be. Some factors which can influence the partition of urinary sulfate are known to be important. The condition of the liver which conjugates the phenols, and of the kidney which excretes them, certainly is important. The availability of sulfate in the body is probably less important. Little is known about the role of the diet and the presence of intestinal stasis. The Bureau of Mines group set an arbitrary level of 80 per cent of inorganic sulfate, figures below those indicating exposure to benzene. This is probably unjustified. Scott and Hastings in a large series of workers in various industries found cases of inorganic sulfate below 70 per cent, where there was no question of exposure to benzene, but what is needed is an even larger series of cases to establish the frequency of occurrence of any partition of urinary sulfate, so that in the end the probability of the chance occurrence of any fraction of sulfate can be expressed. In spite of all these difficulties, Dr. Kammer and his co-workers have shown what should be done to cope with such a situation.

DR. R. R. SAYERS, Washington, D. C.: I was glad to have the statements made by the authors, bringing out important points. One is that it is useful in the control of the exposure and that it is not a specific diagnostic procedure and is not intended as such; however, if, on examination of a group of workers by this method one finds that inorganic urinary sulfates are below 80 per cent of the total, it is time to see what control measures must be made; however, in some cases it will be found that the man had no exposure to benzene at any time. His condition may be due to something else entirely; but, if he is having exposure to benzene, the control measures can be corrected. The authors called attention to the point that just chemical analysis of the air are grab samples usually and do not indicate the efficiency of the control system; furthermore, if they did, the man is not in one spot at all times and he may be exposed to various quantities through the day, and it is the total exposure which is measured by the urinary sulfate method. The method should be further investigated. I think it may be useful.

DR. J. M. McCULLOUGH, Crockett, Calif.: I have used the white count in exposure and have found a definite drop in counts when a man was exposed within thirty-six hours of the time the count was taken. That count comes up within a week to ten days, but the exposure would stop. I can't give percentages, but occasionally where leaks have occurred the men would get enough to feel a certain amount of prostration. I have never had a case in which complete prostration occurred, but the men have complained of weakness and dizziness and some exhaustion, and the count was found down around 5,000. Where normal counts of from 8,000 to 10,000 had been observed,

they would drop to 5,000 and occasionally as low as 4,300. That comes up after five to seven days' time. I should like to hear from some one who has had the same experience.

DR. A. G. KAMMER, Indiana Harbor, East Chicago, Ind.: The only question raised in this discussion was the matter of white counts. We haven't seen a depression in the white counts. In case 1 the absorption found its expression in a lowered red count, and it is my opinion that a complete count would help more than just routine white counts.

RECENT STUDIES ON THE PATHO-
GENESIS OF WERLHOF'S
DISEASE

MARIO TORRIOLI, M.D.

AND

VITTORIO PUDDU, M.D.

ROME, ITALY

The relation between the spleen and the contents of platelets in circulating blood have for a long time now been admitted on purely clinical and empirical bases (therapeutic action of splenectomy in Werlhof's disease, thrombopenia secondary to primitive splenomegaly). Some series of researches carried out in the last few years seem to allow an experimental framing of this relationship and an interpretation of its nature.

In 1933 a series of researches on the subject was begun in the laboratory of this clinic. We¹ were able to establish that extracts of spleen taken from patients affected by Werlhof's disease applied in highly concentrated doses injure the megakaryocytes in cultures in vitro of the bone marrow of guinea pigs. The extraction was performed with the technic used in extracting trephones and therefore contained the whole hydrosoluble fraction dissolved, and the other fractions were suspended or in emulsion. So up to a point it could be called a total extract. From control researches carried on at the same time, it became evident that the normal spleen contains a similar principle, though less active, and later on that the same principle exists in the liver, lungs, red muscle, lymphatic glands and epiploon (Torrioli and Galeazzi,² Dimitrova³). Each normal organ and tissue proved on examination to possess a different degree of activity; according to the percentage of megakaryocytes injured in culture, they can be classed on a decreasing scale in the following order: epiploon, spleen, lymphatic gland, lung, liver, heart and red muscle. The hypothesis was advanced that these various degrees of activity were in proportion to the contents of the reticulo-endothelial tissue of the various organs and tissues examined.

In the meantime we⁴ were able to establish that, while the splenic artery blood serum was almost totally devoid of the toxic principle on the megakaryocytes, the splenic vein blood serum in subjects affected with Werlhof's disease contained this principle in high concentration. Torrioli and Pusic⁵ subsequently noticed

that large doses of a protein-free aqueous extract of a normal spleen, injected intravenously into rabbits, strongly reduced the contents of platelets in their circulating blood. By varying, according to a given scale, the doses of extract in the culture of bone marrow, Torrioli and Belleli⁶ were ultimately able to prove that high doses injure the megakaryocytes while smaller doses not only do not injure them but, on the contrary, stimulate them, so that sometimes they assume an aspect similar to that which is considered as peculiar to the genesis of the platelets.

Taken as a whole, this set of researches seemed to point to a principle acting on the megakaryocytes, capable at high doses of injuring them and at reduced doses of stimulating them. This principle, elaborated by the principal reticulo-endothelial centers, seems to exceed normality in Werlhof's disease and to be likely to return to normality by means of splenectomy.

The results of researches quite recently carried out in the laboratories of Johns Hopkins Hospital in Baltimore appear to be in perfect unison with the ones already mentioned. By means of intravenous injections of a spleen digested extract from a patient with Werlhof's disease, Troland and Lee⁷ repeatedly obtained a strong diminution of the platelets in the circulating blood of rabbits. Troland and Lee seem to arrive at the conclusion that the thrombopenic substance is specific of the splenic tissue in Werlhof's disease. On this point, however, we wish to make a reservation. In the first place it should not be forgotten that a decrease of platelets in circulating blood was obtained by Torrioli and Pusic⁵ with normal spleen extract. In the second place the controls used by the American authors were thyroid tissue, myomatous uterus which, like muscular tissue, has almost no effect at all on the thrombopoietic system, and finally a spleen from a patient with Banti's disease and from one with hemolytic disorder, both of which differ widely from normal spleen as regards structural and functional plan. It is to be hoped that experiments with extracts of normal spleen and other normal organs will be made on a larger scale in order to set on a perfectly clear basis the point regarding the specific character of this principle, a point which appears to us of the utmost importance for the next step toward the future solution of the problem. We have mentioned the fact that this has already been done by Torrioli and Pusic,⁵ who, adopting for the extraction a technic of their own, have been led to results similar to those of Troland and Lee with the spleen in Werlhof's disease though on a smaller scale. Naturally it is also necessary to control in this same sense the extracts obtained with the technic of the Baltimore authors.

As to the chemical nature of the thrombopenic substance, we are obliged to admit that, at the present moment, we are unable to define it precisely. Neither our technic of extraction nor the technic of the American authors will allow any useful statement on this side of the question.

SULFANILAMIDE EXCRETION IN HUMAN BREAST MILK

AND THE EFFECT ON BREAST-FED BABIES

H. L. STEWART JR., M.D.

AND

J. P. PRATT, M.D.

DETROIT

Popularity of sulfanilamide in medical literature has created unusual interest and suggested broad therapeutic application. Originally introduced as a chemotherapeutic agent for the treatment of puerperal sepsis due to the beta hemolytic streptococcus, its value in that field has been repeatedly demonstrated. Many publications have emphasized the toxic effects on the patient from overdosage or on susceptible persons. On account of the frequent administration of sulfanilamide to nursing mothers, the following important questions are raised: 1. Is it excreted in breast milk? 2. If so, in what amounts? 3. What effect may be expected on the nursing babies? To answer these questions, quantitative estimations of free sulfanilamide were made on the blood and milk of nursing mothers and on the blood and urine of breast-fed babies.

The presence of sulfanilamide has been demonstrated in many body fluids and tissues. It is excreted chiefly

Chart 1.—Free sulfanilamide in the blood and milk of a mother on 60 grains (4 Gm.) of sulfanilamide daily. Blood indicated by solid line, milk by broken line. On a uniform dosage with normal renal function, the sulfanilamide concentrations in the blood and milk are closely parallel.

in the urine. Concentrations in the cerebrospinal fluid, pleural effusions, digestive juices, ascitic fluid and prostatic fluid are only slightly lower than in the blood stream. Marshall, Emerson and Cutting¹ have shown that in dogs sulfanilamide is present in all body tissues in approximately equal values, with the exception of bone and fat. From the investigations mentioned, one might infer that sulfanilamide is present in human breast milk. Quantitative studies were reported first by Hepburn, Paxson and Rogers² and recently by Adair, Hesseltine and Hac.³ Since toxic manifestations may occur during the administration of sulfanilamide, it is important to know in what concentration the drug is excreted in breast milk and the effect it has on the nursing baby.

METHOD

Twenty-eight normal convalescent women were studied during the first eight postpartum days. Only

those who secreted enough breast milk for adequate nursing were used. The technic of administration was based on the study of absorption and excretion of sulfanilamide as reported by Marshall, Emerson and Cutting,⁴ who found absorption complete in man in four hours after oral administration. The cases were divided into two groups according to dosage: Ten cases in group 1 received a daily total of 30 grains (2 Gm.) administered in doses of 5 grains (0.3 Gm.) every four hours; eighteen cases in group 2 received 10 grains (0.6 Gm.) every four hours for a total daily dose of 60 grains (4 Gm.). The initial dose was given at 10 a. m. on the first day. Specimens of blood and milk were collected daily immediately preceding the 10 a. m. nursing period. Quantitative determinations of free sulfanilamide were made according to the method of Marshall⁵ in the Chemical Laboratories under the supervision of F. W. Hartman. Although the method as outlined by Marshall was applicable to the analysis of the blood, a minor addition to the technic was necessary in order to obtain a clear solution for colorimetric study of the milk. Following the diazotization and coupling with dimethyl- α -naphthylamine, the milk solutions were turbid. If clear solutions were not obtained by being passed once through a high grade filter paper, refiltering through the same filter paper cleared the solution satisfactorily for comparison with the standard.

Urine and blood studies of the baby were made while nursing from mothers receiving 60 grains daily. In six babies, twenty-four hour urine specimens were collected from the fourth to the sixth day. The blood of eight babies was collected on the seventh day.

All mothers were closely observed for evidence of toxicity. Subjective symptoms were carefully noted. Objectively, attention was directed toward evidences of acidosis, optic neuritis, toxic dermatoses and gastrointestinal disturbances. When cyanosis was conspicuous, sulfhemoglobin and methemoglobin studies were made. Routine temperature and pulse and respiration rates were recorded and frequent complete blood counts were performed.

Sulfanilamide is excreted principally in the urine. With impaired renal function, urinary excretion is diminished and continued administration of the drug results in its accumulation in the body. In every case in this series the urine was normal during the antepartum and postpartum states.

Relative to the baby, particular consideration was given to (1) weight gain, (2) intake of breast milk, (3) general appearance and behavior, including persistent cyanosis, skin rashes, unusual lassitude or irritability, vomiting and diarrhea.

RESULTS

The patients in group 1 receiving 30 grains a day showed concentrations of free sulfanilamide in the breast milk which corresponded closely to the estimations in the blood stream. The level in the blood and milk ranged between 2 and 4 mg. per hundred cubic centimeters. Mothers who secreted an average of 400 cc. of breast milk daily thereby excreted approximately 8 to 16 mg. of sulfanilamide in twenty-four hours. As the blood level rose or fell in an individual case, the concentration obtained in milk tended to change propor-

tionally. The results in a case typical of this group are recorded in chart 1, in which the milk and blood values were almost identical. In only one case of our entire series was the level in the blood conspicuously higher than in the milk (table 1).

In group 2 the concentrations of the blood showed a greater daily variation, averaging from 4 to 7 mg. per hundred cubic centimeters. The values of free sulfanilamide in the milk closely paralleled those of the blood. The estimated average total daily excretion of the drug ranged from 16 to 28 mg. In contrast to the first group, concentration in the milk was generally equal to or slightly higher than the blood. Although tending to show an individual variation in milligrams per hundred cubic centimeters of sulfanilamide in the blood and milk, most results were similar to the case illustrated in chart 2.

It was with interest that we observed the results during the interval preceding engorgement of the breast. In only one case of the entire series was a high concentration of the drug present in the breast milk during

Chart 2.—Blood indicated by solid line, milk by broken line. In contrast to the first group (chart 1), concentration of sulfanilamide in the milk was generally equal to or slightly higher than the blood. Drug discontinued on the eighth day.

this period. A value of 7.8 mg. was found in the milk and 3.2 mg. in the blood. The following day the milk contained 4.1 mg. and the blood 4.4 mg., and on subsequent days the concentrations were closely parallel.

Marshall and his associates have shown that sulfanilamide rapidly disappears from the blood stream when the drug is discontinued. This study confirms theirs and also shows that the milk concentrations fall rapidly when oral administration is discontinued.

Administration of 60 grains of sulfanilamide daily to mothers produced only traces of the drug in the blood of nursing babies. Quantities ranging from 1 to 2.6 mg. per hundred cubic centimeters were excreted in the urine over a twenty-four hour period.

All babies of the entire series showed (1) satisfactory weight gain, (2) average intake of breast milk and (3) normal appearance and behavior when compared with the other babies in the nursery. From these clinical observations and the mentioned laboratory studies, it is believed that the doses and duration of administration of sulfanilamide in this study to nursing mothers were not sufficient to cause toxic manifestations in the baby.

5. Marshall, E. K., Jr.: Determination of Sulfanilamide in Blood and Urine, *Proc. Soc. Exper. Biol. & Med.* 36: 422 (April) 1937.

Varying degrees of cyanosis without sulfhemoglobin and methemoglobin was the most frequent toxic manifestation in the mothers. Mild toxic effects including general malaise, headache, occasional nausea, vertigo and tinnitus were noted in several cases. Slight elevations of temperature in five cases might have been attributed to the drug. No case of acute hemolytic anemia or agranulocytosis was encountered. Evidences

of apparent acidosis, optic neuritis, toxic dermatoses, jaundice or other gastrointestinal disturbances were lacking.

COMMENT

In 1907 Bucura⁶ wrote that very few drugs have been demonstrated in human breast milk. Since then, thorough studies on excretion of drugs in breast milk have been occasionally reported. Most work has been directed toward qualitative determinations for a drug after oral administration. The observations of the effect on the breast-fed baby have been based on objective clinical phenomena. Recently Kwit and Hatcher,⁷ Tyson and his co-workers⁸ and others have published interesting and valuable studies on the excretion of drugs in breast milk. These workers made chemical analyses of the mother's milk but did not analyze the blood and urine of the baby. Their opinions concerning the effect on the baby were based on clinical observations. The recent publication by Hepburn, Paxson and Rogers² included quantitative determinations for sulfanilamide in the milk of the mothers and the urine of the babies. Neither concentration of the drug in the blood of the baby nor the clinical effects of sulfanilamide on the baby were stated. Adair, Hesseltine and Hac³ reported a quantitative study of sulfanilamide in breast milk. They also experimented with rabbits. In their summary they state: "Until more is known of the tolerance of the human fetus and of the newborn for sulfanilamide, the drug should be administered only with the utmost caution during pregnancy and during the period of lactation. If administered to the mother, breast feeding should be discontinued during the period that sulfanilamide is excreted in the milk"

Long and Bliss,⁹ Jones¹⁰ and Flexner¹¹ state that it is difficult to determine the dose for babies, but they estimate that a total of 1 Gm. of sulfanilamide to 10

pounds of body weight should be received during the first twenty-four hours. If one wishes to administer this amount to the baby by way of the mother's milk, enormous doses will be required. For the average baby taking 400 cc. of breast milk in twenty-four hours, a theoretical concentration of 250 mg. per hundred cubic centimeters of breast milk would give the desired 1,000 mg. daily dose. In this study, the highest dose received by a full time nursing infant on breast milk containing 7 mg. of sulfanilamide per hundred cubic centimeters was 28 mg., or approximately one-half grain (0.03 Gm.), in twenty-four hours. The amount of the drug received by the baby is so small, therefore, that therapy by way of the breast milk is not logical.

Sulfanilamide has not been pointed out as a drug of special value in the treatment of impetigo contagiosa. In four babies not included in this series impetigo developed. Sulfanilamide was administered to the mothers, and the babies received breast milk containing from 5 to 7 mg. per hundred cubic centimeters of the drug for a period of several days. No appreciable change in the course of the infection was noted.

CORD BLOOD AND AMNIOTIC FLUID

Six women received 5 grains of sulfanilamide every four hours throughout labor. At the time of delivery, specimens were obtained from the maternal blood, from the cord blood and, in three instances, from the amniotic fluid. The cord blood and amniotic fluid contained sulfanilamide in amounts closely paralleling the maternal blood concentrations, as shown in table 2.

CONCLUSIONS

1. Free sulfanilamide is excreted in human breast milk in concentrations closely corresponding to the values present in the blood stream.
2. When oral administration of sulfanilamide is discontinued, the concentration in the milk rapidly falls.
3. Breast-fed babies of full time nursing mothers did not show clinical evidences of toxic manifestations when

TABLE 2.—Sulfanilamide Concentrations in Maternal Blood, Umbilical Cord and Amniotic Fluid

| Case | Free Sulfanilamide, Mg. per 100 Cc. | | |
|-----------|--|------|-------|
| | Blood | Cord | Fluid |
| E. H..... | 5.2 | 5.0 | ... |
| L. B..... | 3.2 | 3.0 | ... |
| T. R..... | 2.8 | 2.4 | ... |
| G. B..... | 1.5 | 1.3 | 1.3 |
| A. P..... | 4.7 | 2.7 | 3.3 |
| G. R..... | 0.9 | 0.8 | 1.0 |

sulfanilamide was present in breast milk in concentrations of 7 mg. per hundred cubic centimeters. Traces of the drug were present in the blood of the baby. The urine of these babies contained amounts varying from 1 to 2.6 mg. per hundred cubic centimeters during a twenty-four hour period.

4. A nursing baby cannot obtain an adequate therapeutic dose through the milk of a mother receiving an average clinical dose.

5. Sulfanilamide was present in the cord blood and amniotic fluid of six women following the oral administration of 5 grains of the drug every four hours throughout labor.

Clinical Notes, Suggestions and New Instruments

RESPONSIBILITY AND NEW METHOD FOR RECORD- ING DETAILED LABOR DATA

JOHN C. HIRST, M.D., PHILADELPHIA

Safe and effective amnesia and analgesia in labor must be based on individualization of each parturient patient, which in turn must depend on accurate, frequent and complete observations permanently recorded. Otherwise the patient will either be deprived of relief or, with the fetus, will be subjected to unwarranted and possibly dangerous or even fatal depression. With almost universal adoption of sedation of some sort in hospital practice, the obstetrician assumes greatly increased responsibility even in the simplest confinements and should obligate himself to show evidence of adequate personal attention to the progress of labor, not only to justify his policy of conservatism or interference, as the case may be, but also to establish a foundation for the choice of hypnotic as well as for the time, amount and method of administration, particularly in complicated labors.

In spite of these obvious truths, most labor records, even in large maternities, favor incomplete and haphazard notations divided between entries on the history by an overworked house physician and irregular recordings by a nurse who may or may not be interested or experienced in obstetrics. Ample proof of the inadequacy of such methods may be observed in the reports of maternal and fetal deaths (many of which are due to the analgesic or anesthetic used) in any mortality committee meet-

This system proved so satisfactory that it was utilized for further study in the Methodist Hospital and in the Preston Retreat. In the last named maternity it has remained in regular use, recently as an integral part of a folder-type history form instead of as a separate sheet. Later, on recommendation to the staff of the Philadelphia Lying-in Hospital, it was adopted there for trial in modified form and approved again recently with further modifications, having been used with a constant labor attendant in every instance of analgesia in many thousand labors. From this experience it may be stated that the system is simple and workable, with no disadvantages; I would say that it has been the means of saving a good many patients from overdosage, of allowing safe repetition of sedation in resistant persons and of providing a connected sequence of events in prolonged parturition otherwise impossible.

CONCLUSIONS

1. The use of labor amnesics and analgesics carries responsibility that can be met only by accurate, frequent and complete permanent recordings by a constant obstetric attendant and physician.
2. A specialized form here illustrated is recommended for this purpose.

500 North Twentieth Street.

THROMBOPENIC PURPURA FOLLOWING ALLYL-
ISOPROPYL-ACETYL-CARBAMIDE (SEDORMID)

DAVID B. HILL, M.D., NEW YORK

This report is submitted to record the occurrence of the manifestation of purpura in two patients who had been using sedormid (allyl-isopropyl-acetyl-carbamide) as a hypnotic.

CASE 1.—A woman aged 70 complained of the presence of peculiar looking spots in her mouth and on her skin on the morning of Nov. 21, 1936. She presented numerous purplish areas due to extravasation of blood beneath the mucous membrane, inside the lips and cheeks and on the soft palate and edge of the tongue. Several of the lesions were 1 cm. in diameter and some were oozing blood at the edges. Many petechiae were present in the skin of the extremities and body, and ecchymoses at the right elbow and forearm, with smaller areas on the other extremities. The pains experienced in both shoulders during this attack suggested probable extravasation into the joints. Physical examination was otherwise negative. The temperature and pulse rate were normal.

Examination of blood taken that morning was as follows: hemoglobin (Dare) 85 per cent or 13.6 Gm., red cells per cubic millimeter 4,530,000, color index 0.93, platelets per cubic millimeter 180,000, white cells 9,800; polymorphonuclear neutrophils 81.6 per cent (mature 78.4 per cent, immature 3.2 per cent), lymphocytes 14.4 per cent, large mononuclear cells 3.2 per cent, eosinophils 0.8 per cent and basophils 0.0. Coagulation time (Lee and White) was nine minutes and bleeding time three and one-half minutes.

During the succeeding forty-eight hours a few new lesions appeared in the mouth and on the skin, after which recovery was uninterrupted until complete about ten days later.

In June 1936, sedormid had been prescribed for insomnia and one tablet had been taken every night for a brief period. During the summer the patient was in the country and had no need of a sedative. About one week before this attack she had resumed the use of one sedormid tablet at night to promote sleep.

The cause of the patient's manifestation was at once suspected and treatment consisted of rest and the omission of any further use of sedormid. There has been no recurrence, and the patient is enjoying good health at the present time.

CASE 2.—A woman aged 48 was referred to me by a nose and throat specialist Feb. 5, 1937, because for several days she had been having epistaxis, in the treatment of which he had been unsuccessful. He expressed the belief that the major cause must be constitutional rather than local.

Having had the recent experience with case 1, I at once told him to ask her if she had been taking sedormid, and her answer

[illegible]

Record for insuring regular labor observations. Later additions include temperature, ingestions and evacuation, thereby obviating separate nurses' records.

ing, where it is often a matter of much difficulty for the patient's own physician to present a clear picture of the situation and an absolute impossibility for a stranger to unravel and evaluate the various responsible factors.

Impressed with these matters, I offer a system for recording labor observations which from thorough trial in several hospitals has proved a protection to patient, physician and nurse. The method is based on a new type of record first introduced in the obstetric department of the hospital of the University of Pennsylvania during the fall of 1935 for the purpose of continuing observations on barbituric acid amnesia (begun in 1928)¹ in labor. Through the courtesy of Eli Lilly & Co. a full time graduate nurse was employed as an obstetric attendant to note the differences in reaction chiefly with sodium pentobarbital, paraldehyde with butyl alcohol, and sodium propyl-methyl-carbonyl-allyl barbiturate-Lilly (seconal), according to the specially prepared form illustrated.

was in the affirmative. She had been upset, early in January 1937 by the death of a relative, and a friend had suggested that she use sedormid to promote sleep. For several weeks she had taken one tablet at night.

On examination, the patient showed epistaxis from a slow oozing over the entire nasal mucous membrane. Petechiae were present on the lips, soft palate, tongue and skin. There were several areas of ecchymoses on the extremities. Sedormid was at once discontinued. No new lesions developed. Epistaxis had ceased after twenty-four hours and recovery was prompt. There has been no recurrence.

A MODIFICATION OF THE ASCHHEIM-ZONDEK TEST

THOMAS F. WALKER, M.D., AND DORA V. H. WALKER, M.D.
GREAT FALLS, MONT.

The Aschheim-Zondek test for the diagnosis of pregnancy is one of the most satisfactory, useful and accurate laboratory tests that have been developed within a generation.

Rats have largely replaced mice, used in the original test, since only one rat is used for the test rather than five mice.

The Friedman test has the advantage over the Aschheim-Zondek test in that the results are known in from twenty-four to thirty hours rather than on the fifth day, as in the original Aschheim-Zondek test. However, when large numbers of tests are performed the inconvenience of keeping on hand large numbers of isolated rabbits is a matter of no small concern.

We have found that, if young female white rats are used, the test may be completed in thirty hours, the advantage in time of the Friedman test thus being gained without the inconvenience of keeping isolated rabbits on hand.

We have used young female white rats from 30 to 45 days old. Instead of injecting 0.5 cc. of urine subcutaneously twice a day on three successive days and killing the animal on the fifth day, we have injected 1.5 cc. of urine subcutaneously (in the groin) three times in a single day and killed the rat thirty hours after the first injection. As a control, we have in each instance carried out the test on another rat which received two subcutaneous injections of 1.5 cc. of urine daily for three days and was killed on the fifth day.

In 153 tests in which both methods were used, the results were identical. In no case in which a positive result was secured by giving two subcutaneous injections of 1.5 cc. of urine daily for three days and killing the animal on the fifth day was the test other than positive in the rat that had received only three injections of 1.5 cc. of urine and been killed thirty hours after the first injection.

We believe that this slight modification of technic "speeds up" the Aschheim-Zondek test without affecting its accuracy and makes it more practical than the Friedman test.

The detailed technic of our modification of the Aschheim-Zondek test follows:

1. The morning specimen of urine is collected.
2. A female white rat from 30 to 45 days old is injected with 1.5 cc. of urine three times during the day.
3. Thirty hours after the first injection the animal is killed with chloroform and the ovaries are examined.
4. In positive cases the ovaries are enlarged and hyperemic and show hemorrhagic follicles.

ANTEPARTUM CARE

CLINICAL LECTURE AT SAN FRANCISCO
SESSION

OTTO H. SCHWARZ, M.D.

ST. LOUIS

Although the United States was one of the first countries to develop antepartum care, much yet remains to be done to have such care reach the great majority of the mothers in our land. No better introduction can be given a discussion of antepartum care than to recall the classic statement of Williams concerning this subject, that from a biologic point of view pregnancy and labor represent the highest function of the female reproductive organs and should be regarded as a normal process. However, when one recognizes the marked changes in metabolism during pregnancy and the numerous changes that take place in the expectant mother, the borderline between health and disease is not so distinct as at other times. Derangement so slight as to be of little consequence in ordinary circumstances may readily be the precursor of pathologic conditions which may seriously threaten the life of the mother and her child. Antepartum care, therefore, may be defined as the care and supervision of the pregnant woman; the broader term maternal care would be better to include both labor and the puerperium.

I shall not go into great detail concerning this care—these details are enumerated in every standard textbook—but shall emphasize only the more important points that this care involves. It is obvious that the patient must report as early as possible in pregnancy. A thorough general physical examination should be carried out early in pregnancy in order to recognize or eliminate medical complications. The medical complications that give most concern are heart disease, tuberculosis, diabetes and hyperthyroidism. They are in themselves problems, but superimposed on pregnancy they represent a serious picture and each case becomes an individual problem which must be carefully managed.

Fortunately today, with improved medical care, the pregnant woman can go through this ordeal in most instances with little or no increased danger as regards her life expectancy, and only occasionally does the question of termination of pregnancy arise. In a clinical practice these patients are best seen on special days by both the obstetrician and the internist. In order to have a better understanding of the existing condition and its prognosis, it is best to hospitalize the patient when first seen, the length of stay in the hospital depending on the severity of the condition. Cardiac and nephritic patients are brought in several times during their pregnancy, and it is ideal to have them in the hospital at least two weeks before delivery. Active tuberculosis in pregnancy should be handled as active tuberculosis is handled under any other condition. If the proper treatment is instituted early, these patients during pregnancy do as well as and sometimes better than in the nonpregnant state. However, it must be borne in mind that unrecognized active tuberculosis in pregnancy will

progress rapidly in the untreated state. Therefore it is important to recognize early active lesions.

Diabetes today, so far as the mother is concerned, can be well managed, but in spite of the use of insulin the fetal mortality had not been improved until very recently. Labor is quite an ordeal for the fetus of the diabetic mother and, owing to marked derangements in carbohydrate metabolism, hypoglycemia frequently develops in the fetus after birth and, unless it is counteracted, may result in death. Babies of diabetic mothers are large as a group and contain more fat than those of normal mothers. Difficult labor, therefore, is frequently encountered. On this account it has been suggested in various quarters that pregnancy be terminated by cesarean section, under local anesthesia, at about thirty-eight weeks. Figures show a marked lowering of fetal mortality in cases handled in this way.

Repeated pregnancies with medical complications should definitely be avoided. Although the mother may go through one pregnancy with little additional risk, this does not usually hold for repeated pregnancies, so that in any event future conception is highly undesirable, not only from the point of view of the mother's health but for economic and social reasons as well.

It is important to recognize pelvic abnormalities early in pregnancy; not only the contracted pelvis but the presence of pelvic tumors should be determined because, if intervention is indicated, they can best be handled early in pregnancy. In the first trimester of pregnancy it is important to have information concerning the position of the uterus. If it is retroverted, it should be brought forward and held there with a properly fitting pessary until the patient is a little over twelve weeks along. If the patient is not seen in the first few weeks of pregnancy, the retroverted uterus will frequently adjust itself; but occasionally it may become incarcerated, giving rise to serious signs and symptoms, owing to the cervix rising up behind the symphysis. Under such circumstances the urethra is markedly lengthened and pressure is exerted at the base of the bladder. This leads at first to frequency of urination and then to retention of urine. In extreme cases there may be complete anuria with a greatly distended bladder. On account of the markedly lengthened urethra, the bladder can be emptied only by means of a male catheter.

The classification of the pelvis should be determined by routine examination. Although marked rachitic deformities are seen only occasionally today, certain types of moderately contracted pelves, namely the generally contracted and simple flat, give rise to dystocia. Arrangements should be made for the hospitalization of patients presenting such conditions so that they may have the proper test of labor under the best conditions. It may be said here that antepartum care and supervision are of no great value unless preparations are made for a safe and intelligent conduct of labor.

To emphasize this point, one need only refer to the statistics on maternal mortality, and most striking of all these is the Rothert report of some five years ago. This report consisted of a study of the causes of death for a two year period in fifteen states. In this area there were 7,380 deaths due to puerperal causes, of which 2,948, or 40 per cent of the deaths, were due to infection and 1,900, or 26 per cent, were due to the late toxemias of pregnancy. Antepartum and postpartum hemorrhage were third, but fortunately comprised only 6.7 per cent of the total maternal mortality.

It is obvious that, with good antepartum observation and proper care at the time of delivery, many of these infections could be reduced, but it is incorrect to state that they could be reduced to a negligible minimum for the simple reason that many infections which occur during difficult and traumatizing labor occur from organisms that the patient harbors herself.

On the other hand, the prevention of serious cases of toxemia of pregnancy can be readily accomplished by the proper antepartum care, as is shown by the low incidence of these conditions in any well conducted private practice. It is interesting to point out that in the 7,380 cases there was information obtainable on 5,636 cases as regards antepartum care. According to this report, antepartum care is divided into three grades: grade 1 is accepted as adequate antepartum care, grade 2 indifferent antepartum care, and grade 3 poor antepartum care. In this group of 5,636, only 725 were given grade 1 care, 499 were given grade 2, and 1,337 were given grade 3, and there was no antepartum care in 3,025.

It is also interesting to mention conditions under which patients dying of the toxemias of pregnancy were first seen. In the whole group, 35 per cent were first seen in coma or convulsions. Patients coming in poor condition brought the total up to 60 per cent, and only 20 per cent were in good condition when first seen. The white patients in the city showed the best record, but in this group 20 per cent were seen in coma and convulsions and up to 45 per cent in poor condition. White patients in rural districts were somewhat worse off, 30 per cent being admitted in coma and convulsions and up to 60 per cent in poor condition. This is interesting, because in most large cities adequate facilities for proper antepartum care are available, and it means only that patients who had such service available did not take advantage of it. Of the Negro patients in this group in the rural districts 60 per cent were admitted in coma and convulsions and in the city 45 per cent. Of the Negro patients in this group in poor condition 90 per cent were admitted from rural districts and 80 per cent from the city.

What can be accomplished by good antepartum care is outstandingly shown in the symposium on the prevention of eclampsia which was given at a recent meeting of the American Gynecological Society, but before taking this up I wish to make a few remarks concerning the treatment of eclampsia once this condition is present in a fulminating state. Although there has been marked improvement in the treatment in most cases, the mortality rate is still high. Twenty years ago in most clinics it was between 20 and 30 per cent, but today it is in the neighborhood of 10 per cent. Some few, such as McCord of Atlanta, present figures as low as 6 per cent for a large series of cases.

The cause of eclampsia is not known, but the treatment is far from empirical because the treatment aims at abolishing certain existing signs and symptoms. Obstetricians have relied chiefly on elimination and the use of intravenous dextrose and magnesium sulfate, resorting to cesarean section under local anesthesia only if the patient does not improve on the conservative regimen. I do a cesarean section in about one in every six cases. That no ideal method of treatment has yet been found is shown clearly in that at every clinic in this country the treatment varies to some degree, but magnesium sulfate and dextrose seem to be the most freely used procedure.

In normal pregnancy there are many physiologic changes. In many instances these become greatly exaggerated in the late toxemias and especially in eclampsia. Of these, marked retention of sodium chloride and edema are very striking. It has long been known that in limiting the intake of salt during the last half of pregnancy the physiologic rise in weight can be checked. In eclampsia, edema and retention of salt are most marked, and although the hepatic lesion, which is a specific one in eclampsia, is found in most cases at autopsy, this condition is probably terminal and has little or nothing to do with the onset of the disease, the retention of salt and edema being in all probability more concerned with the oncoming convulsions.

What can be prevented by good antepartum care is very definitely shown in the figures of de Snoo of Utrecht, Holland, which were presented at the meeting of the American Gynecological Society in 1937. Over a ten year period in his clinic there were 20,000 deliveries with twenty-seven puerperal deaths and not a single death due to eclampsia. This is an unusually good record and, of course, may not be repeated in the next 20,000 births. In these 20,000 clinical births, eclampsia developed in twenty-one mothers and in almost every instance it was due to lack of cooperation on the part of the patient. This remarkable record was obtained chiefly by putting the patients on absolutely salt-free diets as soon as signs of toxemia developed. For some time I have been restricting salt in such cases, but not quite to the degree emphasized by de Snoo. I have emphasized also the abstinence from meat protein and good elimination through the bowels. During a period of six years in which there were approximately 12,000 deliveries, 217 cases of preeclampsia developed. Of these 217 cases, eclampsia developed in twenty-six, with two deaths. The patient's lack of cooperation precipitated the onset in most instances.

With the remarkable record of de Snoo in mind, it behooves the profession to emphasize further the value of antepartum care, so far especially as the late toxemias of pregnancy are concerned. In St. Louis there are at least ten well established clinics, and in spite of the fact that these are available to the public they are not used to full advantage by the patients. A discussion by Daily in the aforementioned symposium indicates how improvement can yet be made so far as toxemias are concerned. He states that in the years 1930-1935, 36.8 per cent of the maternal deaths were due to the late toxemias of pregnancy, and in a comparison of 1930 with 1935 there was a marked decrease in the number of maternal deaths, eclampsia accounting for 54 per cent of this decrease. In 1935 in urban areas it was reduced to 15.4 per cent, while in the rural districts it was 23.6 per cent of all puerperal deaths.

In a report by Dr. Franz Arzt of the analysis of deaths from puerperal causes for three years in St. Louis, twenty-eight maternal deaths, or 13.5 per cent, were due to eclampsia. During this time there were approximately 40,000 births. In the cases handled exclusively by the municipal antepartum clinics for the three years, numbering 4,479, there were no deaths due to eclampsia among the white patients and three among the Negroes. Although this record for the city as a whole is comparatively good, further improvement further education of the public is necessary. The patients must be instructed to come early and cooperate fully with the outline of care that is prescribed.

Perhaps one of the reasons that cooperation is not as good as it should be is that the procedures which actually prevent the development of fulminating eclampsia are so commonplace, namely the restriction of meat, catharsis and limiting of salt. If the patient could be made to see how very much these rather commonplace procedures will do to ward off serious cases of toxemia, the death rate due to the development of eclampsia, with its definite mortality, might be reduced to an almost negligible minimum.

THE CHEMISTRY OF VITAMIN C

C. G. KING, Ph.D.

PITTSBURGH

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

IDENTIFICATION

A primary requisite for studying the chemical nature of vitamin C was provided by Holst and Frölich¹ when they observed that the guinea pig could be used as an experimental animal for the study of scurvy. The experimental diets and general technic developed by Cohen and Mendel² and La Mer, Campbell and Sherman³ then made it possible to measure antiscorbutic activity in a satisfactory quantitative manner, free from interference by deficiencies in other essential nutrients. Attempts to isolate the vitamin from natural products encountered great difficulty, however, because of its extreme sensitiveness to destruction by oxidation.

By 1931 many investigators, particularly Zilva and his associates,⁴ Bezssonoff and his associates⁵ and King and his associates⁶ had succeeded in concentrating the vitamin to such a degree that approximately 1 to 2 mg. of solids daily served to protect young guinea pigs from scurvy. The isolation of the vitamin from lemons and its identification as "hexuronic acid," having a protective level of 0.5 mg. a day, by Waugh and King⁷ in 1932 was followed within a few weeks by a report from Svirbely and Szent-Gyorgyi⁸ that 1 mg. daily of

"hexuronic acid" prepared from adrenal glands was protective against scurvy. The protective value of hexuronic acid prepared from adrenal glands by Kendall,⁹ using an entirely different procedure, was then shown by Waugh and King¹⁰ to be identical with that of the product from lemons, thereby essentially removing any question of contamination of the original crystals by another active substance. In their next paper Svirbely and Szent-Gyorgyi¹¹ also found the minimum protective level of their product to be 0.5 mg. a day. Within a short time the identity of the vitamin was independently confirmed by several laboratories, particularly those of Tillmans,¹² Vedder,¹³ Nelson,¹⁴ Harris¹⁵ and von Vargha.¹⁶ The compound $C_6H_8O_6$, having the same general formula and many properties in common with other hexuronic acid lactones, had been prepared from cabbage, oranges and adrenal glands in 1928 by Szent-Gyorgyi¹⁷ in studying tissue respiration systems, but there was no knowledge of its antiscorbutic value previous to the work published in 1932.

It may be interesting to note that isolation of vitamin C resulted, in one laboratory, from four years of systematic fractionation of lemon juice, based entirely on biologic assays, and that in another laboratory biologic assay for vitamin function was reported five years subsequent to the isolation of the vitamin as hexuronic acid, a silver nitrate-reducing agent in tissues, and two years after its negative assay as a hormone.

STRUCTURE AND SYNTHESIS

The structural formula of the vitamin was established in 1933, primarily by Haworth, Hirst and his associates,¹⁸ Karrer and his associates,¹⁹ Micheel and Kraft²⁰ and von Euler and Klusmann,²¹ using material obtained from adrenal glands and paprika, supplied largely from Szent-Gyorgyi's laboratory. Before the structure was established with certainty, Reichstein, Grussner and Oppenauer²² succeeded in synthesizing the *d*- and later the *l*- form of the acid. Some delay and confusion occurred in working out a satisfactory graphic formula, because the vitamin represented an entirely new type of configuration for a hexuronic acid lactone. Before the structural formula had been established, so that the acid could be named according to its relationship to known sugars, Haworth and Szent-

Gyorgyi suggested the name "ascorbic acid"²³ to connote its antiscorbutic nature. The American Medical Association introduced the name "cevitamic acid" expressly to avoid this connotation.

Synthesis was first accomplished from *l*-xylose, I. On treatment with phenyl hydrazine *l*-xylose yields the osazone, II. This compound on hydrolysis yields *l*-xylosone, III. Treatment of the latter with hydrocyanic acid produces the nitrile of the *l*-xylosone, IV, which on hydrolysis is converted first into the intermediate 2-ketogulonic acid, V. In an acid medium lactonization and enolization occur and vitamin C itself, VI, is produced.

I. *l*-xyloseII. *l*-xylosazoneIII. *l*-xylosoneIV. nitrile of *l*-xylosone

V. 3-ketogulonic acid (intermediate, not isolated)

VI. vitamin C (ascorbic or cevitamic acid)

Several different methods of synthesis have been published in detail and others have been disclosed only in patents. The catalytic and electrolytic reduction of *d*-glucose to sorbitol on a commercial scale, followed by selective fermentation to *l*-sorboside, provides a basis for commercial synthesis at low cost. A number of procedures have been followed for converting sorbose to the intermediate sorburonic or 2-ketogulonic acid. The more important structurally related compounds are *d*-glucose, *d*-glucuronic acid, *l*-gulose, sorbitol, *l*-sorboside and sorburonic acid.

Comparison of the formulas for *d*-glucose, *l*-gulose and *l*-sorbose serves to illustrate the transition in series from *d*- to *l*- in going through the *d*-glucose \rightarrow sorbitol \rightarrow sorbose steps, since the *d*- or *l*- nomenclature is based on the configuration of the asymmetric carbon farthest from the saccharide group. Antiscorbutic activity is contingent on the *d*- configuration of C-4 (responsible for its dextrorotation) and the *l*- configuration of C-5. A number of sugar derivatives having structures analogous to that of ascorbic acid (2,3-enediol-4-lactone) have been prepared and shown to have similar chemical properties. Zilva²⁴ has given a good summary of the relative physiologic values of closely related synthetic substances, the most active being *l*-rhamnoascorbic acid, which had one fifth of the antiscorbutic value of ascorbic acid. None of the other compounds examined had more than one tenth of the value of ascorbic acid. *d*-Ascorbic acid had no antiscorbutic value.

TYPE REACTIONS

The acidic properties of the vitamin are due to dissociation of an enolic hydrogen rather than to opening of the lactone ring. Methylation with diazomethane involves the enolic groups (C-2 and C-3) first, and further treatment with dimethylsulfate forms ethers from the other two OH groups (C-5 and C-6). Esterification of the alcohol groups on C-5 and C-6 can be accomplished readily with acyl halides. The carboxyl group does not enter into any of the common laboratory reactions of the vitamin in either aqueous or alcoholic solution. The lactone ring of dehydroascorbic acid apparently opens more readily than that of ascorbic acid. Condensation with aldehydes, acetone and other ketones takes place under the influences of very mild dehydrating agents, giving rise to stable compounds that can be crystallized readily from acetone, alcohol and other organic solvents. Triphenylmethylchloride forms an ether (trityl) readily on carbon-6. Heating with strong mineral acids gives rise to furfural and carbon dioxide.

The reactions of greatest general interest are those dealing with oxidation and reduction. Barron, De Meio and Klemperer have shown that in aqueous solution below p_H 7.6 the vitamin is not oxidized on exposure to air unless the reaction is catalyzed by traces of copper²⁵ or some other activating agency. Although copper had been widely recognized as a very effective catalyst, their results were of special interest in showing that the vitamin is nonautoxidizable within the normal p_H range of plant and animal tissues. The interdependence of p_H , anions and concentration of copper in their relation to the rate of aerobic oxidation has been demonstrated by Lyman, Schultze and King.²⁶

As would be expected from its oxidation-reduction potential, the vitamin is reversibly oxidized by a great many organic compounds such as methylene blue, quinones and the indophenol dyes, and by inorganic reagents such as Cu^{++} , Fe^{+++} , Hg^{++} , Ag^+ , Mn^{+++} , $Fe(CN)_6^{--}$, NO_3^- , WO_4^{--} , H_2O_2 , and I_2 . A discussion of the use of oxidizing agents for the quantitative esti-

mation of vitamin C in tissues will be found in the section on methods of assay. The dry crystals of vitamin are stable on exposure to air and daylight at room temperature through a period of several years. They tend to become buff colored without undergoing appreciable decomposition. In aqueous solution, however, the rate of aerobic oxidation is greatly accelerated by exposure to light, especially in the presence of flavins.

Dehydroascorbic acid, VII, the reversibly oxidized product formed from ascorbic acid, is fairly stable in acidic aqueous solutions, e. g. below p_H 4, but in faintly acid (p_H above 4), neutral or alkaline solutions it undergoes an irreversible rearrangement, giving rise to another strong reducing substance. It is this second strong reducing substance, as shown particularly by the work of Borsook and his associates,²⁷ that gives rise to oxalic acid, VIII, and *l*-threonic acid, IX, on further oxidation.

Reduction of dehydroascorbic acid can be accomplished readily by H_2S , cysteine, glutathione and the "fixed-SH" groups associated with proteins. The rates of reduction are markedly dependent on the relative concentrations and the p_H of the solutions, however. Metals reacting with acids, or hydrogen under pressure with common catalysts do not reduce the product with good yields.

PHYSICOCHEMICAL PROPERTIES

When adequately protected from oxidation, the vitamin can be crystallized from solution in water or the lower alcohols, acetone, ethyl acetate and many other organic solvents. The colorless crystals tend to form dense radiating clusters but may form characteristic plates or needles (monoclinic, pseudo-orthorhombic), depending on the solvent and the rate of crystallization.

Its physical constants are: melting point 192 C.; specific rotation $+24$ degrees in water, 48 degrees in alcohol, without mutarotation; acidic dissociation $pK_1 = 4.17$ (Harris et al.) (or 4.20 cf. Ball), $pK_2 = 11.57$; absorption maximum 260 millimicrons in water, 263 millimicrons in alcohol (Karrer, Hirst, et al.); oxidation-reduction potential (Borsook) at p_H 4.0 and 35 degrees, $E_{\frac{1}{0}} = +0.166$ V. Ball gives $+0.390$ volts for the normal potential of ascorbic acid at 30 degrees, and five minutes for the half life of dehydroascorbic acid at p_H 7.24, 30 degrees. For a detailed discussion of the oxidation-reduction potentials under various conditions, the recent papers of Borsook and his associates²⁷ and of Ball²⁸ should be consulted.

THE PHARMACOPEIA AND THE
PHYSICIAN

LOCAL URINARY ANTISEPTICS

HENRY W. E. WALTHER, M.D.

Professor of Urology, Louisiana State University Medical Center
NEW ORLEANS

This is one of a series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopoeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.

In the application of local antiseptics to disorders of the urinary tract, a twofold purpose must be kept in view; first the destruction of the infecting microorganisms, and second the stimulation of a reaction in the tissues of the patient which will enable him to offer the necessary resistance to the infection. It is now generally recognized that the stimulation of the natural resistance of the mucous membrane of the urinary tract is quite as important as the destruction of the infective agents. If, for example, an antiseptic is wrongly used in the urethra, it may, while slaying the gonococcus, incidentally so damage the normal epithelium as to invite future stricture formation. Rightly used, it will offer the mucous membrane just enough irritation to stir it to defend itself but no more. This happy mean is what the urologist is seeking. In the past the physician's zeal to kill off the intruding organisms often got the better of his discretion and resulted all too frequently in the exhaustion of the patient's powers of resistance by the violent insults to which the delicate membrane of this sensitive tract was subjected.

Much has been learned from past mistakes. It is now known that the medication addressed to these tissues should be the mildest that is consistent with effectiveness. An active participation of the host is essential for the success of attempts at antiseptics. The urinary tract must become the uncongenial place for the habitation of these organisms. This will of necessity be a gradual process, requiring the utmost gentleness and patience. There is no way of knowing in advance the type of reaction that will result from the use of a particular medicament in a given individual. Nothing is more difficult than to estimate the value of an antiseptic in either the prevention or the treatment of a septic process. One must proceed with the greatest care in each individual case.

One of the greatest difficulties at the outset lies in the fact that the infecting organisms have usually penetrated so deeply into the tissues before treatment has been started that the local antiseptic cannot follow them. In one's choice of treatment, one has to consider not only the bacteriostatic powers of a given substance and the degree of irritation that it is likely to produce in the mucous membrane but also its capacity for penetrating the latter. Few of the older antiseptics could exert more than a superficial action on the epithelium, and too often this structure was ruthlessly destroyed without the organisms sharing in the destruction.

In this study I shall review the most important of the local urinary antiseptics in use at the present time and shall then make an attempt to evaluate their usefulness in the separate portions of the urinary tract. In

order to do this I shall take up in succession the consideration of acute and chronic urethritis, acute and chronic cystitis and acute and chronic pyelitis (pyelonephritis), in relation to the appropriate local antiseptic treatment of each.

The substances used in local antiseptic treatment of the urinary tract fall, in a general way, into groups of (1) mercurials, (2) silver salts, inorganic and organic, (3) dye therapy and (4) chemotherapy, although the members of these groups overlap at some points. In addition, and not falling precisely into any one of the groups, there are such time-honored remedies as potassium permanganate, boric acid, phenol, cresol, trinitrophenol (picric acid) and various other more or less widely used drugs.

ANTISEPTIC TREATMENT

These various substances may be used either as irrigations or as instillations or injections. The purpose of an irrigation is not only the introduction of a medicament to the tissues but also, and in large degree, the removal of debris and detritus. It is held by some urologists that the nature of the medicament introduced is relatively inconsequential, the main idea being to cleanse the tract involved. Solutions introduced as irrigations are comparatively weak, their frequent repetition rather than their strength being relied on to make them efficacious. An instillation, on the other hand, consists of a small quantity of stronger concentration of the antiseptic substance designed to be retained in an organ from five minutes to several hours, as the case may be, to exert its full medicinal properties on the tissues. The determination of the proper strength is of overwhelming importance. Some of these substances cannot be used in a strength that is bactericidal and yet one sees the infection clear up in response to them. Evidently the good results are due to some reaction within the mucous membrane.

Acridine (U. S. P.).—Neutral acridine is a popular drug now in common use. Chemically it is 2, 8 diamino-10-methylacridinium-chloride and 2, 8 diaminoacridine. When properly diluted it is not irritating, and in selected cases its use has given extremely satisfactory results. If used in too strong concentration it readily invites stricture, owing to chemical inflammation of the tissues. It is deceptive, and many patients will not tolerate it. Too long continued or too frequent use is also to be avoided. One injection a day is all that should be risked.

Mercurochrome (N. N. R.).—This dye has been decidedly popular for a good many years as a urinary antiseptic for local use. It is the disodium salt of 2:7-dibromo-4-hydroxymercurofluorescein. If administered in low dilution not more than once a day for not more than three days in succession it is not irritating. It generally requires a follow up by some accompanying milder drug, such as mild protein silver. In too large dosage, however, or if given too often, its irritative properties come to the front.

Gentian Violet Medicinal (N. N. R.).—This is one of the rosaniline dyes, with low toxicity for the tissues and excellent capacity for penetration. Its relative harmlessness has been proved by the observation that tissue cultures are not injured by concentrations that arrest bacterial growth. It is particularly successful in anterior urethral infections of a nonspecific nature.

Potassium Permanganate (U. S. P.).—This most common of all antiseptic astringents acts directly on the gonococcus. It has in addition an indirect action

by causing edema of the mucosa of the urethra, which helps to destroy the organism. In the presence of organic material potassium permanganate is rapidly reduced to inactive manganese dioxide, setting free nascent oxygen. It is during this process that the gonococcal action occurs. If much organic material of a nonbacterial nature (such as pus and blood) is present, the reduction is quickly accomplished and there is no more power to destroy cocci. Its germicidal power is, therefore, not high, but because of its admirable capacity for cleansing it continues to remain in favor. By its ability to oxidize dead matter, plugs of mucus, pus and dead epithelium are loosened up and proper drainage is established. It should be used as hot as the tissues can bear. Its action is exerted more in the anterior than in the posterior urethra.

Zinc Permanganate (N. N. R.).—This lesser used zinc salt of permanganic acid should be better known. It resembles the potassium salt in its oxidizing properties (only it gives up oxygen more easily than does the potassium salt) and is more astringent.

Boric Acid (U. S. P.).—Although in reality not germicidal, boric acid is such an admirable cleanser that no discussion of this kind would be complete without including it. From time immemorial it has been a dependable agent for lavage of cavities in which sterile water or saline solution would have been more irritating. The absence of all toxic effect makes it an ideal irrigating fluid where bulk is desirable for cleansing or distention. It is nonirritating, stable and of simple chemical structure. Though not a disinfectant, even in saturated solution, it checks putrefaction and decomposition in a solution of 0.3 per cent. In urologic practice it is used as a routine by many for cleansing of the bladder or urethra before an instillation of some antiseptic substance.

Of all the substances employed today as local urinary antiseptics, the various silver compounds enjoy the widest popularity. Starting with silver nitrate, which still remains as the keystone of the structure of local antiseptics, there is now available a long array of derivatives, each of which has its partisans and all of which produce good results when properly administered.

Silver Nitrate (U. S. P.).—The inorganic salts of silver, of which silver nitrate is the best known and most useful, form resistant precipitates with proteins, so that their local action is easily controlled. The antiseptic effect of silver nitrate is high, its toxicity low. In the presence of the tissues of the body, silver surpasses mercury, since its protein compounds, as well as the colloidal oxides and metallic silver, liberate a small amount of silver ions. The antiseptic action of silver nitrate goes quite deep, since it forms easily soluble double salts of silver albuminates and sodium chloride in the tissues. Its caustic and astringent action may be stopped with sodium chloride. It acts on the urethra by liberating nitric acid and coagulating albumin. It also exerts an indirect influence in stimulating the mucous membranes wherever it is introduced into the urinary tract. A reaction is necessary in the form of slight burning. This irritant character contraindicates its use in some cases but increases its value in others. If any chlorides are present in the urine, it is immediately precipitated in the form of inactive silver chloride. This makes its action on the urinary tract only momentary. It should therefore be reserved for cases in which an irritative or caustic effect is desired.

Out of silver nitrate came derivatives in the form of colloidal suspensions, the use of which in the urinary tract avoids the irritation, pain, astringency and corrosion associated with the inorganic salt. The activity of these preparations is said to be quite independent of their total silver content and is determined by the ion concentration, which differs for different compounds. When antiseptics without irrigation is desired, the direct application of the colloid compounds may have advantages over their indirect production from silver nitrate within the tissues. Some of these colloids retain a certain degree of irritant property, while others become entirely bland. Thus there are strong and mild silver proteins, the former retaining in part the irritant quality of silver nitrate, while the latter have lost it. The clinician has, therefore, at his disposal a wide range of colloidal silver compounds that can be employed to meet the needs of the individual case.

Strong Protein Silver (U. S. P.).—These proteinates have the lowest percentage of silver (from 7 to 8.5 per cent), but in solutions this becomes largely ionized, so that they have the strongest bacteriostatic effect but are also distinctly irritant, though far below the silver nitrate in this respect. The irritant effect of this preparation, originally introduced under the name of protargol, is about one tenth that of silver nitrate, confirming the fact that nearly all the silver is ionized. The strong silver proteins thus lie therapeutically between silver nitrate and mild protein silver. All these colloidal silver preparations consist of finely divided metallic silver in colloidal suspension with a protective colloid of some albuminoid substance to maintain the suspension. They apparently do not penetrate deeply but have a definite antiseptic value on mucous membranes. They act by producing an intense hyperemia, causing a serous exudate and active phagocytosis, which sweeps away both living and dead organisms. All these solutions should be made freshly every day or two, since they deteriorate on standing, and they should be kept in amber colored bottles.

Mild Protein Silver (U. S. P.).—With slight variations this group contains such preparations as argyrol, neosilvol and other colloidal compounds of silver oxide and a protein derivative. It differs from strong protein silver in being entirely nonirritant. It is also less active as an antiseptic but more soothing. The high specific gravity of its solutions facilitates their spreading, enabling them to act as detergents for the removal of pus and secretions. Mild protein silver contains from 19 to 25 per cent of silver. The different brands differ slightly in composition but are essentially equivalent in therapeutic properties, all being mucilaginous demulcents.

ACUTE URETHRITIS

The local antiseptic treatment of acute urethritis naturally falls into two categories, according to whether one is dealing with a gonococcal infection or an infection of nonspecific origin. These again have to be differentiated for purposes of treatment into male and female conditions and, in the male, into treatment of anterior and of posterior urethritis.

Anterior Gonococcal Urethritis.—The commonest acute urethritis is, of course, that due to gonococcal infection in the anterior urethra of the male.

With the first appearance of a urethral discharge, an attempt may be made to abort the attack, if not more than a few hours to a day has elapsed. Either one of the solutions given in prescriptions 1 and 2 may be used for injections.

After the patient has urinated, 8 cc. is slowly injected, to be retained five minutes, then evacuated, and the procedure repeated three or four times. For subsequent treatment in early stages it is used in tenth-normal strength three or four times daily. If the gonococci have not disappeared by the third day, the treatment has failed to abort the infection and further measures must be taken addressed to the acute

PRESCRIPTION 1.—Solution of Mild Protein Silver

| | | |
|------------------------------|---------|------|
| R Mild protein silver..... | 12 Gm. | ʒijj |
| Distilled water, q. s.....ad | 120 cc. | ʒiiv |

PRESCRIPTION 2.—Solution of Strong Protein Silver

| | | |
|------------------------------|------------|-----------|
| R Strong protein silver..... | 2.40 Gm. | gr. xxxiv |
| Distilled water, q. s.....ad | 120.00 cc. | ʒiiv |

(These should be freshly prepared.)

inflammatory stage of urethritis. These will be largely internal. After about three days, when the most acute phase has abated, the hand injections may be resumed, in from one-tenth to one-fourth normal strength. Once a day the physician may instill a more irritative antiseptic, such as neutral acriflavine 1:5,000 or zinc permanganate 1:4,000, of which 6 cc. is to be retained one minute. Many physicians prefer an instillation of potassium permanganate 1:8,000.

Either mild protein silver 5 to 15 per cent or strong protein silver 0.25 to 1 per cent may be instilled. Generally speaking, the strong protein silver may be instilled in strengths of from 0.25 to 1 per cent in the urethra, and the mild protein silver in from 5 to 10 per cent; this should be done every two to four hours, if possible. Solutions should have been recently prepared and protected against light.

When irrigations are used, the agents and their strengths are as follows:

Strong protein silver, 1:2,000 to 1:1,000.
Mild protein silver, 1:1,000.
Potassium permanganate, 1:8,000 to 1:4,000.
Zinc permanganate, 1:8,000 to 1:4,000.
Acriflavine, 1:10,000 to 1:5,000.
Silver nitrate, 1:20,000 to 1:10,000.

Silver nitrate is not so well adapted for anterior as for posterior urethritis but is still used here by some urologists.

As the subacute stage arrives, intravesical irrigations of any of the milder antiseptic solutions are in order.

Nonspecific Anterior Urethritis.—Many of the same local antiseptics are useful in nonspecific infections of the urethra. Instillations of a 1 per cent solution of trinitrophenol have proved beneficial, from 5 to 10 drops being introduced gently into the urethra.

All the colloidal silver preparations find their indication here. The bladder should first be washed with 2 per cent boric acid solution, following which mild protein silver from 5 to 10 per cent or strong protein silver from 0.5 to 2 per cent should be used. Aqueous solution (from 3 to 5 per cent) of calcium chlorate or of resorcinol (0.25 to 1 per cent) is sometimes better than potassium permanganate or the silver salts for local treatment of uncomplicated pyogenic urethritis. They may be introduced either as irrigations or as instillations.

Another antiseptic of low toxicity and marked penetrating power is gentian violet medicinal, which is specific for staphylococcic infections. It may be introduced in 1 per cent solution into the urethra either by instillation or by irrigation. Mercurochrome from 0.25 to 1 per cent and metaphen in oil may also be used in these cases advantageously.

A part of the value of an irrigation is that it distends the urethra and so enables the medication to reach all parts of it. The complete filling of the urethra by a hand injection has a similar effect.

Posterior Urethritis.—In the acute stage of gonorrheal posterior urethritis no local treatment is given until irritant symptoms have subsided. In the subacute stage, urethrovesical irrigations of permanganate from 1:8,000 to 1:4,000 are given, or of silver nitrate 1:10,000. Another substitution recommended is that of zinc permanganate 1:8,000 to 1:4,000 as an irrigation. Deep instillations of silver nitrate 1:10,000 also give excellent results, carried out with the Guyon catheter. Strong protein silver from 5 to 10 per cent may be used if desired instead of silver nitrate.

CHRONIC URETHRITIS

In chronic urethritis silver nitrate has always been the mainstay of treatment. Irrigations with a 1:10,000 solution are useful, or deep instillations of from 0.5 to 2 per cent solutions. Any of the following may be used for irrigation:

Acriflavine, 1:10,000 to 1:5,000.
Mild protein silver, 1:400 to 1:100.
Strong protein silver, 0.25 to 0.5 per cent.
Potassium permanganate, 1:8,000 to 1:4,000.
Zinc permanganate, 1:8,000 to 1:4,000.

Urethritis in the Female.—In gonorrheal urethritis the same remedies are used as in the male, but they are applied by swabbing instead of by injections and are used in greater strength, from 1 to 10 per cent strong protein silver or from 0.5 to 2 per cent silver nitrate every second or third day. Potassium permanganate douches are given.

Nonspecific urethritis in women is usually called cystitis, and not without reason, since the infection is bound to reach the bladder. The term urethrocystitis has been suggested for the combined infection. The cause of this condition is nearly always traumatic. Instillations of mild protein silver from 5 to 10 per cent or of strong protein silver from 1 to 2 per cent afford some relief; mercurochrome from 0.25 to 1 per cent is also used here. Topical applications of silver nitrate from 5 to 75 per cent through the endoscope, although painful, serve to open up the ducts and allow the pent-up secretions to come away. They should not be repeated too often, however. Careful examination in these cases reveals that the primary inflammation is in the small posterior urethral glands. Instillations of mild protein silver from 10 to 50 per cent have also been found beneficial.

ACUTE CYSTITIS

In the most acute stage of cystitis, no local treatment is undertaken. A little later treatment with instillations of mild protein silver may be begun, from 25 to 50 per cent of the mild or from 1 to 2 per cent of the strong. Before instillation the bladder should be completely emptied by voiding, then irrigated with plain sterile water, hot boric acid solution or physiologic solution of sodium chloride. Another useful instillation is mercurochrome 1:100, left in the bladder as long as tolerated.

Bladder irrigations, also begun a little later, and preceded by lavage with boric acid or sterile water, may be done with any of the following:

Silver nitrate, 1:10,000 to 1:5,000.
Potassium permanganate, 1:8,000.
Acriflavine, 1:8,000.

Since silver nitrate is an irritant, its use should be preceded by as well as followed with application of a surface anesthetic such as metycaine. Such irrigations are useful in acute cystitis, provided there are no stones or malignant growths. The dyes may sometimes safely remain in the bladder for two or three hours. If the inflammation is due to some condition producing stasis, such as a stone or a tumor, local treatment will not correct it. Silver nitrate will sometimes clear up cystitis so effectively that its action appears almost to be specific. Since in the strength used (1:10,000) it is not an antiseptic, any action it exerts must be due to some reaction within the mucous membrane.

Nonspecific cystitis without renal or urethral involvement responds well to daily instillation of mercurochrome from 0.5 to 1 per cent, especially in the female. In gram-positive infections of the bladder, irrigations of gentian violet from 1:10,000 to 1:5,000 or instillations of 1 per cent or more have a specific effect on the staphylococcus and certain other types of local infection.

CHRONIC CYSTITIS

In chronic cystitis the usual treatment is distention irrigation with silver nitrate from 1:10,000 to 1:1,000, after the bladder has been washed with a 2 per cent boric acid solution or distilled water; also instillation every other day of from 1 to 2 per cent silver nitrate, if not too painful. Otherwise, one of the silver proteins may be used. Potassium permanganate irrigations 1:8,000, used hot, are frequently beneficial. Mild protein silver from 10 to 15 per cent or strong protein silver from 0.25 to 2 per cent as an irrigation is widely employed. Some urologists still make use of mercury bichloride 1:30,000 for irrigation of the bladder. Mercurochrome 0.25 per cent and acriflavine from 1:10,000 to 1:5,000 are all used, and all give good results as irrigations in properly selected cases; 1:8,000 acriflavine dilutions have been found effective in bladder conditions secondary not only to acute gonococcal urethritis but also to nonspecific urethritis. The gravity method gives the best control of pressure when used with a blunt nozzle when this is practicable. While the chief purpose of bladder irrigations is a mechanical cleansing, the action of soothing medicaments on the bladder mucosa and the relief of tenesmus are also important objectives.

ACUTE PYELONEPHRITIS

In the very acute stage of infections of the renal pelvis, no local antiseptic treatment should be undertaken. Drainage by ureteral catheter is indicated, however, and when the inflammation becomes subacute pelvic lavage is of great importance to prevent chronicity. It is sometimes followed by dramatic improvement, which may be due to the action of the antiseptic employed but may be the result of improved drainage through mechanical dilation of the ureter. Before proceeding with kidney pelvis lavage, one should aspirate the contents of the pelvis. From 5 to 10 cc. of an antiseptic solution is then slowly injected and allowed to escape. Then more is injected and the process repeated a few times. The favorite lavage is done with silver nitrate 1 per cent. If this is too painful, as is often the case, some other substance of less irritating nature may be injected, such as mercurochrome 1 to 5 per cent or gentian violet 1 to 5 per cent, the last named being used when the infective agent is gram positive. When the urine becomes clear these irrigations may cease.

Acriflavine 1:4,000 is an efficient antiseptic in the renal pelvis, but one must exercise due caution not to produce a chemical irritation of the mucous membrane. Irrigations of acriflavine from 1:10,000 to 1:4,000 may be alternated with irrigations of potassium permanganate 1:6,000 and mild protein silver 5 per cent.

CHRONIC PYELONEPHRITIS

In chronic pyelonephritis, renal lavage is the mainstay of treatment. The same general types of antiseptics are used as in subacute cases but not oftener than twice a week. It should be emphasized that when good results are observed it is a mistake to increase the dosage in the hope of still better results. On the contrary, excessive stimulation does harm, and the aim should be rather to decrease the amount of antiseptic gradually as the condition of the mucous membranes improves. After lavage of the kidney pelvis with silver nitrate solutions the mucosa is often found congested, its epithelium desquamated and a polymorphonuclear exudate present, giving evidence of an active inflammation. That this is an aid in eliminating a mild infection is borne out by numerous clinical reports. It is in this irritant or caustic effect rather than as an antiseptic that silver nitrate excels. One should take care that this caustic effect is not overdone. Experience and judgment are required to know when the chemical effect has reached the limit of the patient's tolerance. The course of treatment must often be protracted. Sometimes silver nitrate in 1 per cent strength achieves a lasting cure after one or two treatments, but often it has to be repeated once or twice a week for months. When there are no results, it is probable that the kidney substance is also involved along with the pelvis. In such cases from 3 to 5 cc. of a 1 per cent solution of mercurochrome is often effective, since mercurochrome has the property of penetrating rapidly through the tubules and cortical substance to the periphery of the kidney. Many subacute and chronic types of focal pyelonephritis respond satisfactorily to one form or another of lavage of the kidney pelvis. Formaldehyde 1:2,000 (in adults) and mild protein silver from 5 to 15 per cent have been credited with curative action.

SUMMARY

In combating infections in the urinary tract by means of antiseptic solutions applied locally (or topically) our purpose is twofold; namely, to destroy or at least retard the growth of specific invading bacteria and also to stimulate a reaction within the tissues involved so as to increase resistance at the site of the inflammation. It is not so much what particular agent is employed for this purpose as how it is employed. The clinician must ever be on guard against the use of antiseptic solutions so strong as to destroy the tissue he aims to preserve. He must remember that any substance sufficiently potent to kill bacteria outright also kills, at the same time, the tissue harboring those organisms. Only by employing the mildest solutions consistent with effectiveness can he hope for the desired results. Different persons react differently to particular medicaments. Youth will tolerate certain procedures that the aged patient, under no circumstances could endure. The personal equation should dictate in selecting and then perfecting oneself in one or two of the most popular local urinary antiseptics. It is better to know thoroughly the possibilities (and limi-

tations) of one or two of these agents than to use a score of them haphazardly. At best, this form of therapy is only an adjunct in the scheme of treatment; yet, when instituted with agents mild in their reaction, employed with the greatest gentleness and persisted in conscientiously, their place in urologic practice remains secure. Finally, and this urologists consider most important, self medication in the form of hand injections or irrigations, carried out by the patient himself, is to be emphatically discouraged.

Whitney Bank Building.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

H. A. CARTER, Secretary.

S. O. S. OXYGEN THERAPY HUMIDIFIER ACCEPTABLE

Manufacturer: Oxygen Equipment and Service Company, 919 North Michigan Avenue, Chicago.

The S. O. S. Oxygen Therapy Humidifier is designed to humidify oxygen used in oxygen therapy by breaking the stream of gas into minute bubbles. According to the firm, this enables the oxygen to be more thoroughly saturated with water vapor than is possible with the ordinary wash-bottle humidifier.

S. O. S. Oxygen Therapy
Humidifier

The S. O. S. Oxygen Therapy Humidifier consists of a brass tube of heavy sheet metal, $3\frac{1}{16}$ inches in diameter, onto which is silver soldered a bottom and a heavy cast bronze top. On this top is silver soldered another brass tube 3 inches in diameter which hangs within three-sixteenths inch from the bottom. In the center of the head there is a heavy pipe which extends down close to the bottom. At the lower extremity of this pipe there is a diffusion head which consists of several felt washers which are tightly packed. The oxygen is forced through these washers into the water, which breaks up the stream of oxygen into minute bubbles. These rise to the surface through one hole in the inside tube directly opposite the outlet. The oxygen must then flow around a space between the two tubes before passing through the outlet leading to the catheter. This (the firm states) very effectively traps any drops of water which might happen to be picked up.

A water level glass is mounted on the side of the unit and it is necessary to keep the level in sight at all times. The unit is filled through a petcock mounted on top of this glass. The petcock is opened and held to a flow of water. To empty, the petcock is opened and the unit turned upside down.

The firm states that the humidifier will produce from 80 to 90 per cent saturation of water vapor to the oxygen passing through. This permits pharyngeal insufflation over long periods of time without irritation to the mucous membranes in the nasal passages.

The S. O. S. Oxygen Therapy Humidifier was examined by an investigator acceptable to the Council. Tests were made to substantiate its stated efficiency as a humidifier. With regard to construction, it appeared to be substantially made.

The resistance in this unit is as follows: 4 liters, 58 mm. of mercury; 6 liters, 74 mm.; 8 liters, 82 mm.; 10 liters, 100 mm.

The absence of any sort of flow meter makes it undesirable to use this humidifier on an oxygen line but this is not important when the S. O. S. Oxygen Therapy Humidifier is used on large cylinders, as the reducing valve should be equipped

with a flow meter. A good flow meter does not appreciably change the rate of flow.

Method of testing: Oxygen was flowed through the unit at a fixed rate for six hours and the amount of water picked up by the oxygen was determined by weighing the humidifier before and after. The amount of water in each liter of oxygen was compared with the factor 0.022796 Gm., which is the amount of water vapor in one liter of oxygen 100 per cent saturated at room temperature. The efficiency varies somewhat with the rate of flow, the temperature of the room and the time the apparatus is used. If it is used for only a few minutes, there is more water picked up per liter than after the water becomes cold.

With 4 liters of oxygen for six hours the average humidity was 81 per cent.

With 6 liters of oxygen for six hours the average humidity was 66 per cent.

The humidifier furnished from 65 to 80 per cent humidity under ordinary conditions. It is not possible to say what the optimal humidity is for every patient. In conclusion, the investigator stated that the humidifier appears satisfactory at present.

In view of the foregoing report, the Council on Physical Therapy voted to include the S. O. S. Oxygen Therapy Humidifier in its list of accepted devices.

COMPREX CAUTERY, ANNIVERSARY MODEL, ACCEPTABLE

Manufacturer: Compres Division, American Cystoscope Makers, Inc., 450 Whitlock Avenue, New York.

The Anniversary Model Compres Cautery and Diagnostic Light is a small portable unit designed for cauterization purposes. It is similar mechanically to the Compres Cautery and light transformer #201 (accepted, THE JOURNAL, May 31, 1930, p. 1760) but has a different housing which is claimed to improve its appearance and convenience. Accessories include a pistol-grip handle with spot light located above the tip and a choice of any of three standard tips. It comes in an ivory or black finish with ivory or green control knobs. The weight is approximately 5 pounds.

Simple operating controls are provided. The cautery and cautery light are connected to the machine by a single plug immediately beneath the on-off switch. Current intensity to the cautery is regulated by a five step control. There is a light regulator which is used both for cautery light and for diagnostic instruments. When the diagnostic light is employed, a double range current is available. The low range provides current for lamps up to 5 volt size; the high range permits utilization of 5 to 10 volt lamps. A single plug fits into the desired terminal outlet. If the diagnostic instrument employs an auto headlight bulb requiring very heavy current, it is plugged into the two outer "cautery" terminals. Then its brilliance is controlled by the cautery regulator instead of the light regulator. The unit operates on alternating current.

The pistol-grip handle, which is boilaile, holds the cautery electrode at a comfortable angle for applications, according to the firm. It is also claimed that the small built-in headlight provides unobstructed illumination of the operating field. It is located above the handle but below the line of vision. Both the cautery and light are said to be shockproof and ground free, in addition to being individually regulated. The cautery tips are triply reinforced to guard against short circuiting.

The unit was investigated clinically and found to render satisfactory service. While the light is convenient for treating lesions in areas where intense illumination is required, shadows are not entirely eliminated.

In view of the foregoing report, the Council on Physical Therapy voted to include the Compres Cautery, Anniversary Model, in its list of accepted devices.

Compres Cautery

SATURDAY, OCTOBER 15, 1933

AMERICAN HOSPITAL ASSOCIATION ESTABLISHES PRINCIPLES FOR MEDICAL SERVICE

At the annual session of the American Hospital Association recently held in Dallas, Texas, the following memorandum was prepared by the board of trustees of that organization and submitted to its house of delegates, which approved both the preamble and the conclusions.

CONCERNING THE PRINCIPLES OF RELATIONSHIP BETWEEN APPROVED HOSPITAL SERVICE ASSOCIATIONS AND THE MEDICAL PROFESSION IN PROPOSALS TO PRO- VIDE MEDICAL SERVICE ON AN INSURANCE BASIS TO HOSPITAL PATIENTS OF LIMITED INCOME

With more than 2,000,000 subscribers enrolled, and with membership increasing at the rate of more than one million per year, hospital service plans approved by the American Hospital Association are not only helping patients to pay their hospital bills, but are also contributing indirectly to the preservation of private medical practice in hospitals.

The prevalent restriction of these plans to semiprivate hospital service, and the omission of any provision for physicians' fees in hospital cases, have placed non-profit hospital care insurance beyond the reach of many employed workers of limited income.

There is a strong demand on the part of these low income groups for the creation of hospital service plans adapted to their means. Medical societies are now studying, and in some cases are preparing to sponsor, group payment plans to cover medical fees of patients of limited means. If these efforts are successful, they will reclaim for private medical practice a segment of medical service in hospitals even larger than that which is protected by existing hospital care insurance plans.

The American Hospital Association believes that efforts by the local medical profession to extend the voluntary insurance principles to medical fees in hospital practice can be assisted by cooperation with approved hospital care insurance plans. Approved plans are urged to offer their cooperation and assistance to this end. Joint efforts will make hospital care available to millions of persons of limited means, who in this manner would pay for both hospital care and medical treatment in hospitals.

The American Hospital Association is prepared to approve periodic payment plans for hospital care and medical service in hospitals which are also approved by the local medical profession and which conform to the following principles:

1. Sponsorship and control by non-profit organizations, representative of hospitals, the medical profession, and the public.

2. Free choice of physician and free choice of hospital consistent with existing relations between approved hospitals and their physicians.

3. Financial soundness and adequate accounting.

4. Equitable payments to physicians and to hospitals.

5. Separate finances and reserves for hospital care and for medical services of attending physicians.

6. Hospital and medical service benefits determined by hospitals and the local profession.

7. Dignified promotion and administration.

The American Medical Association is invited to confer with the American Hospital Association regarding these and related problems with a view to harmonious joint action in the public interest.

Thus the American Hospital Association indicates a willingness to cooperate with the American Medical Association with a view to harmonious joint action in the public interest. It recognizes the right of the physician to control the terms of his service. It recognizes the free choice of physician and free choice of hospital as fundamental to good medical care. It supports the established action of the House of Delegates of the American Medical Association in maintaining separate finances and reserves for hospital care and for the service of the physician.

It is encouraging to have such a statement from the leaders in the field of the hospital, since the hospital is today a center of medical service. The action taken by both the American Medical Association and the American Hospital Association now permits the establishment of cooperative plans for group payment for medical service without invalidating any of those ideals or principles associated with medical care which are vital to the provision of good medical service.

HIPPURIC ACID TEST AS AN INDEX OF HEPATIC DAMAGE

Since the classic investigations by Bunge and Schmiedeberg in 1877 it has been believed that synthesis of hippuric acid takes place in the kidney exclusively. More recent researches make it appear that this synthesis, at least in man, takes place in the liver as well. The conjugation of benzoic acid with aminoacetic acid to form hippuric acid represents one of the several mechanisms by means of which the liver detoxifies certain noxious substances brought to it from the gastrointestinal tract. Quick¹ found that the excretion of hippuric acid proceeded at a constant rate regardless of the amount of sodium benzoate ingested but that such excretion could be greatly increased by the ingestion of aminoacetic acid. He concluded, therefore, that the quantity of hippuric acid excreted per hour represented the maximum capacity of the organism to synthesize aminoacetic acid. Since aminoacetic acid is said to be formed in the liver, diminution in the output of hippuric acid would seem to indicate a

1. Quick, A. J.: The Synthesis of Hippuric Acid: A New Test of Liver Function, *Am. J. M. Sc.* 185: 630 (May) 1933.

lowered hepatic function due to certain types of hepatic damage.²

Quick found in a series of clinical cases that the synthesis of hippuric acid was strikingly diminished in catarrhal jaundice, in syphilitic cirrhosis and in obstructive jaundice of moderately long duration. He concluded that the test offers an approximate quantitative measure of liver damage and that it is a valuable aid in the diagnosis of liver diseases.

Boyce and McFetridge³ in recent contributions emphasize the role of the liver in biliary surgery and its heretofore but little recognized importance in thyroid disease as well as in a number of various surgical diseases. Dinsmore, Lahey, Weller, Beaver and Pemberton, among other workers, pointed out the association of damage to the liver with toxic disease of the thyroid. Lahey stated that the postoperative thyroid crisis was in reality hepatic failure and that the deaths associated with hyperthyroidism were "liver deaths." Bartels of the Lahey Clinic and Boyce and McFetridge utilized the Quick test for determination of the amount of hepatic damage in thyrotoxic cases. Boyce and McFetridge believe that by the application of repeated tests they can safely say at the end of the planned preparation that the patient has become a good risk as far as the liver is concerned, or has become a fair one, or remains a poor one and must be further prepared in anticipation of the drop in hepatic function which their experience with the test indicates may follow any surgical procedure. The practical application of the knowledge thus obtained has been to stress the value of intravenous dextrose therapy as prophylaxis against the thyroid crisis.

Boyce and McFetridge studied as controls a group of presumably normal persons who were to undergo elective operations for conditions not connected with the biliary tract or the thyroid gland. In all cases there was a definite drop in hepatic function after operation, the impairment being most marked with spinal analgesia and least marked with ethylene anesthesia. They are convinced that the Quick test offers a more delicate index of hepatic function than either the bilirubin test or the dye test.

2. In the Quick test for hepatic function 5.9 Gm. of sodium benzoate dissolved in 30 cc. of water is administered one hour after a breakfast consisting of coffee and toast. The patient is then given half a glass of water. Immediately after taking the drug the patient urinates and then collects complete hourly specimens for four hours. These are preserved with toluene, and the hippuric acid content is determined in each specimen. In normal adults the output of benzoic acid, as hippuric acid, is approximately 1 Gm. or more during the second and third hours, and the total for the four hours is from 3 to 3.5 Gm. The estimation of the hippuric acid for clinical purposes is accomplished by transferring to a small beaker each hourly specimen, which is measured and is acidified with concentrated hydrochloric acid to congo red. The solution is vigorously stirred until the precipitation of the hippuric acid is complete and then is allowed to stand for one hour at room temperature. The precipitate is filtered off on a small Buchner funnel or a filter plate, washed with a small quantity of cold water and allowed to air dry. The hippuric acid thus obtained is either weighed or titrated with 0.2 normal sodium hydroxide, phenolphthalein being used as indicator. To obtain the total hippuric acid content one must add to the amount thus obtained the calculated quantity remaining in solution; 100 cc. of urine will dissolve 0.33 Gm. of hippuric acid. In case any specimen exceeds 125 cc. it should be slightly acidified with acetic acid and concentrated on the water bath to about 50 cc. before the hippuric acid is precipitated.

3. Boyce, F. F., and McFetridge, E. M.: Studies of Hepatic Function by the Quick Hippuric Acid Test: I. Biliary and Hepatic Disease, *Arch. Surg.* 37: 401 (Sept.) 1938; II. Thyroid Disease, *ibid.* p. 427; III. Various Surgical States, *ibid.*, p. 443.

The author of the test suggests that vomiting when the test is applied to toxic patients may be a disadvantage. Another disadvantage is that the test cannot be applied in cases of nephritis with nitrogen retention. Quick believes that the well known objections levied against the inadequacy of every liver test do not hold in his case. He believes that certain mechanisms of the liver are so delicate that there is practically no margin of safety. He points to the reduction in the excretion of hippuric acid in catarrhal jaundice, which is out of all proportion to the amount of structural change observed in this disease, as a proof that the mechanism concerned with the synthesis of aminoacetic acid has little reserve. The objection that the test measures only one function of the liver is met by the argument that the various functions of the organism are closely interrelated so that an injury to any one mechanism is apt to affect several others as well. According to Mann, however, conclusive proof is not available to show that the liver is the sole site of the synthesis of hippuric acid. Mann further emphasized that it would be important to study the test in relation to the physiologic state of the liver as well as to have more information with regard to the rate of elimination of hippuric acid in the toxic nephroses which are frequently associated with hepatic damage.

DISABILITIES AMONG EMPLOYEES OF A PUBLIC UTILITY

The study of disabilities among employees of specific industries is contributing information which should be helpful not only to the industrial physician but also to the general problem of disease control and to the formulation of specific preventive and ameliorative measures. Gafafer and Frasier¹ studied disability among employees of the Boston Edison Company as represented by absences due to disabilities lasting one calendar day or longer during 1933 to 1937 inclusive. The causes of disability are broadly grouped into industrial accidents, nonindustrial accidents, respiratory diseases and nonrespiratory diseases. There were altogether 16,241 total years of exposure with 17,628 absences lasting one calendar day or longer over the five year period. These absences totaled 133,022 days of disability. The frequency of absences by years showed a practically stationary trend for both males and females, the trend for the former being on a lower level.

The yearly rate for industrial accidents among male employees since 1934 has shown a decidedly downward time trend and a slightly lower trend for nonindustrial injuries. For the entire period the annual number of days of absence per person for all disabilities was 7,518 for males, with an average number of days per absence of 8.35 for the entire period. The corresponding rates for women were 10,855 and 5.96 respectively. The

1. Gafafer, W. M., and Frasier, Elizabeth S.: Frequency and Duration of Disabilities Causing Absence from Work Among the Employees of a Public Utility, 1933-1937, *Pub. Health Rep.* 52: 1273 (July 29) 1938.

diseases and conditions which caused the largest number of days of disability per male employee were "influenza and grip" 1.2 days, "nonindustrial injuries" 0.6 days, and "all other diseases and conditions" 1.2 days. The largest annual number of days of disability for females were due to "influenza and grip" 1.7 days and to "all other diseases and conditions" 1.4 days. Among the male employees the shortest average duration per absence is shown for "colds and coryza," 2.8 days, and the longest for "industrial injury," 28.5 days.

Remarkable differences are shown in the duration of disability in calendar days for the two sexes. For all disabilities the one day absences among women were nearly three times as numerous as among men, while two day absences were twice as frequent. One day disabilities due to nonrespiratory and nondigestive diseases occurred more than seven times as often among the females as among the males; this difference cannot be explained entirely by the presence of dysmenorrhea, since disregard of absences caused by this condition indicates a frequency among the females still four times as great as that among the males. The differential did not hold proportionately for absences of longer duration, since only 205.6 absences per thousand males and 313.6 absences per thousand females extended through the seventh day. Within this one industry there was a wide variation in frequency of absences. The highest rates during the period among male employees were shown by linemen, followed by meter readers, repairmen, helpers and chauffeurs. Trouble men, engineers, division heads and station operators had comparatively low rates of absences due to disability. Among women, office cleaners averaged approximately three absences per person annually and the rate for female clerks was almost twice the rate for male clerks. Telephone operators among women experienced a slightly lower rate than male telephone operators. Approximately 45 per cent of the days of disability among the men occurred during the first seven days after onset and for women the corresponding percentage was 52.

This study was made possible by the fact that in 1913 the company inaugurated a liberal disability benefit plan which provided for payment of wages in full or in part during disability, beginning with the first day of absence. During the second six months of membership, an employee is allowed accumulated sick leave of one day a month at full pay. After the first year of membership, full pay for continuous disability is allowed for fifteen weeks; beyond this time from three fourths to one fourth of the employee's wages are paid, the period of payment depending on the number of years of employment with the company.

Perhaps the most important feature of this report is the fact brought out that 45 per cent of disability among men and 52 per cent of disability among women is of less than seven days in duration. Nearly half of the disabilities are therefore so brief, relatively speaking,

that with rare exceptions the economic burdens which they produce could be carried relatively easily either by the employee alone or by the company alone. Judging from this experience, it would be the other half in which illnesses exceeding one week in duration and especially when extending into further weeks, months or years that must inevitably cause the greatest economic strain on an individual, his family, the company and the public. Might it not, therefore, be more advisable to exempt the first one, two or even three weeks of disability from sick benefits and to employ the savings toward the protection of those who may be faced with more serious hardship? Sufficient information should now be available in many industries so that such a modification could be studied and possibly placed into effect exempting the relatively benign disabilities from benefits and concentrating on those which are truly economically crippling.

Current Comment

HEIGHT OF AMERICAN WOMEN

The common impression that the typical American woman has been growing taller has been subjected to a recent brief analysis.¹ Women accepted for "standard" insurance by the Metropolitan Life Insurance Company between 1922 and 1934 showed an average height (with shoes) of 5 feet 4½ inches (162.7 cm.) in middle adult life when full growth had been attained. This figure is identical with that obtained in two earlier life insurance studies based on the material of several companies covering the years 1885-1908 and 1909-1927. There is, however, some evidence that women in the younger ages insured in 1932 and 1935 had a greater average height than those insured in 1920-1923, so that future averages may change. Although these "averages" argue against an increase in height in recent years, they are not in conformity with the observations of Bowles on the heights of college graduates of four women's colleges, or the studies at Stanford University and Barnard, which do indicate an average increase in height for college women. This apparent discrepancy may be explained, perhaps, by differences in the race stocks which make up the populations in question. The average heights are generally greater for western European stocks than for southern and eastern European stocks. Since there has been a definite change in the proportions of various stocks composing the population in the last fifty years, with an increasing proportion of persons from the shorter ones, the life insurance figures may have been affected by this factor. The sharp curtailment in immigration during and after the war with the reduction in number of shorter foreign born women and the intermingling of racial types will probably tend to overcome the effect of this factor. Hence it is likely that in the course of a generation the average height of women in the population as a whole will show a substantial increase paralleling to a greater degree that already shown by studies of women in college groups.

ORGANIZATION SECTION

PRESS COMMENT ON THE SPECIAL SESSION OF THE HOUSE OF DELEGATES

The special session of the House of Delegates of the American Medical Association developed some specific conclusions regarding the future trend in medical practice and also in relationship specifically to the National Health Program. The reactions of the press of the country to these decisions of the House of Delegates should interest every physician. In general, comments were highly favorable to the American Medical Association. Thus the Cincinnati *Star* said:

The attitude of the A. M. A. toward what is loosely called "socialized medicine," should be clearly understood. Its first concern has been to safeguard the standards of private medicine in order to protect the public health. It has insisted upon the right of the patient to select his own physician. It has opposed the hiring of physicians either by private groups or by the government. It has always opposed, and its house of delegates opposed again at Chicago, the New Deal proposal for a compulsory health insurance tax because such taxation would lead to political control and manipulation. At the same time, it now realizes that private medicine, while preserving intact its traditional standards, must exert all its energy and ingenuity to meet the demand for more adequate medical care for the masses of the people.

In the past the A. M. A. has been on the right side but has not always made its point of view clear to the public. The Chicago meeting should be the beginning of a new era, in which the medical profession will show that its opposition to state medicine and to any outside control of medicine is based not on self-interest but solely on solicitude for the public health.

The Detroit *News* sees a trend toward liberalism:

Organized medicine, nationally and in Michigan, through the house of delegates of the American Medical Association and the similar body representing the Michigan Medical Association, has materially modified its former stiff opposition to extension of medical facilities under Government auspices. . . . A medical departure in the direction of liberalism is reflected, we think. Acting unanimously, the physicians show themselves responsive to conditions which have been under study for years. A striking fact the studies developed is that, while needs for their services were shown, thousands of capable doctors do not find employment enough to return them a decent living.

The Chicago *Drovers' Journal* fears the entrance of politics into medical care:

There are plenty of arguments for and against the proposition of federal medical service, but it all simmers down to whether or not the service is well administered and not permitted to fall into the hands of the politicians. We are all familiar with the way all kinds of service deteriorates when the spoilsman secure control and this seems to be the chief danger. No reputable and conscientious physician wants to see his profession dragged into the mire of politics.

Medical service is one of the most important and necessary services rendered to mankind and whenever it is socialized or regimented, it becomes more or less subject to political influences. It is the poor people who would suffer rather than benefit from political practitioners.

The Indianapolis *News* commends the fair solution of the problem reached by the House of Delegates:

The resolutions adopted by the house of delegates of the American Medical Association, which met at Chicago in special federal public health plan, testify at once to the willingness

of physicians to make the sacrifices for which their profession is notable and to engage in a political contest for the preservation of their integrity and the welfare of all the people who are in need of medical attention. They declared positively against federal compulsory sickness insurance. This plan would call for a tax on pay rolls and the use of the money to finance medical attention, under political control, for the insured people. It would subordinate the doctor to the politicians and it might even involve the forcing of doctors to prescribe medicines and treatments controlled by politicians. The final effect might be to victimize the sick and enrich the politicians at their expense. . . . The delegates, representing the 110,000 members of the association, have offered a fair solution of this important problem. Their resolutions imply a fundamental interest in the health of the people and the protection of the sick from political exploitation.

The comment of the Indianapolis *Star* was:

The general aim of the American Medical Association is to help the citizens to help themselves. Government subsidy of control over group hospitalization plans is opposed. The country, furthermore, does not need and should not want a complicated, bureaucratic political system of dealing with medical care. All who need attention should have it but that care should not be made the pretext for regimenting as well as expending the public health service.

In Florida, the Miami *Herald* commented:

The trend of the times has been to some sort of socialized medicine. The *Herald* neither approves nor condemns the theory. But it has felt the medical profession owed it to itself to guide the movement, and not let it become the tool of politicians to the detriment of the doctors and to the damage of the masses whom it purports to protect.

In Paducah, Ky., the *Sun Democrat* appreciates the physician's point of view:

Representatives of the American Medical Association meeting in Chicago to diagnose the medical requirements of the needy prescribe among other things that additional hospital facilities be utilized more fully, that a greater degree of public aid for medical care be extended the under privileged, and that compulsory health insurance be avoided as injurious to the body politic.

The recommendations are constructive. They represent the considered judgment of experts in consultation on a problem with which they are thoroughly familiar by virtue of first hand experience. . . .

The relationship between the doctor and his patient is a highly personal one. Curing the sick is not a cut and dried matter like painting a house or driving an automobile. Scientific knowledge is required, of course; but so, too, are tact, patience, psychology, and fortitude on both sides. Doctors realize this better than anyone, and they are quick to resent outside interference from any source.

In Youngstown, Ohio, the *Vindicator* said:

The points of agreement are so many and cover so wide a field that they offer a basis of cooperation which probably will satisfy most laymen. It will be better to proceed on that basis, for the present at least; if the changes which the A. M. A. approves work well enough to indicate that a still further extension of government aid in the health field is desirable, it will come inevitably. Meanwhile the government will have the cooperation of the medical profession, without which no public health plan can be wholly satisfactory.

For a time a too conservative leadership in the A. M. A. undermined public confidence in the organization. Considering

the present evidence of a profound change in the medical attitude toward public health, the people probably will be willing now to put at least as much faith in the advice of their doctors as that of their politicians. The government should go forward on the basis provided by the association's very liberal concessions, and leave more sweeping changes to a time when further experience with "socialized medicine" has made the proper path clearer.

In Cleveland the *Plain Dealer* said in an editorial which was widely copied:

By its action Saturday at Chicago the house of delegates of the American Medical Association goes a long way to refute the criticism, heard in many quarters, that the association in its zeal to protect existing professional methods, ignores the plight of a vast number of Americans who now lack adequate medical service because they can not afford to pay for it at the going rates. . . .

The New York *Times*, as might have been anticipated, conceded in a grumbling manner that progress had been made toward a liberal attitude on the part of the House of Delegates of the American Medical Association. The *Times* said under the heading "Medicine Steps Forward":

Both physicians and the public cannot but approve the decision of the House of Delegates of the American Medical Association to recede from its previous position and, on the whole, to endorse the Government's program with the exception of the provision for compulsory health insurance. Hospital insurance of the three-cents-a-day type, cash indemnity insurance which is supposed to meet the heavier costs of serious illness, the expansion of workmen's compensation laws to cover occupational ills, the utilization of Federal and State funds to bring medical care to the indigent—these proposals, once repudiated, are now apparently accepted in principle. Even more important is the obvious willingness of the Association to assume the lead in laying down the new health policy and an implied intention of doing what it can to keep politics out of the kind of medical care that the poor are to receive.

Gratifying as this progress may be, crucial issues are still untouched. The plight of the class that barely earns enough to pay for food, shelter and clothing and has nothing left over wherewith to pay the doctor will undoubtedly be relieved. What of the many who cannot pay even reduced physicians' fees but can set aside regularly something for medical treatment? They must turn to the public hospitals or private charity. Yet the Association advocates more efficient use of

existing hospital facilities in one breath and in another illegally insists that hospitals should not provide medical care. Moreover, workmen's compensation is to be expanded to include sickness benefits, but employers and employees must have nothing to do with salaried or contract medicine.

The public is waiting for a plan which will enlist all voluntary agencies in coping with the problem of illness before taxation is invoked. Cooperatives, clinics of the Mayo and the hospital type where physicians practice in groups, contract medicine whereby physicians on a salary or higher compensation basis are enabled to minister to the sick employees of a manufacturing company can be very effective. Must experimentation in these democratic directions still struggle under legal disabilities largely of organized medicine's creation? More concessions must here be made before the country will be convinced that the need of taxation has been reduced to an inescapable minimum.

Obviously, the editorial writer for the New York *Times* is still uninformed as to the basic requirements for good medical practice.

The Washington, D. C., *Post* said:

The A. M. A. did not withdraw its objections to cooperative health associations. On the contrary, its resolution says: "Experience in the operation of hospital service insurance or group hospitalization plans has demonstrated that these plans should confine themselves to provision of hospital facilities and should not include any type of medical care." That statement leaves much to be desired. Yet it is obvious from the more positive resolutions adopted that the A. M. A. as well as many individual doctors are taking a more liberal view of the profession's obligation to society.

That fact stands out more significantly than any other development at the delegates' emergency meeting in Chicago. The urgent need for more adequate medical care within the lower income groups is not open to question. If that deficiency is to be corrected full cooperation of the organized medical profession is certainly essential. Indeed, leadership of the movement by the profession may afford the only assurance of continued progress.

If the Administration is wise, therefore, it will welcome the concessions made by the governing body of the A. M. A. and attempt to extend the area of cooperative effort for better public health. The association made a serious mistake when it set out to undermine cooperative health experiments. But that mistake is not likely to be corrected by prosecution of the Medical Association under the anti-trust laws. Even if the courts could be convinced that this professional organization is restraining "trade," it is doubtful whether the result would be constructive.

MEDICAL ECONOMIC ABSTRACTS

SICKNESS UNDER NATIONAL HEALTH INSURANCE

At the health congress of the Royal Sanitary Institute, July 11 to 16, 1938, Dr. A. B. Walker, Regional Medical Officer of the Department of Health for Scotland, discussed "The Duration of Incapacitating Sickness" under national health insurance. He summed up much of the material covered in his paper in the following early paragraph:

"The National Health Insurance Act was designed principally as an instrument to improve the standard of curative medicine in general practice by replacing the old club system of contract practice. It was reasonable to hope that this act, together with the improved environmental services, by providing early and effective treatment would have some effect not only in diminishing the amount and duration of disabling illness but also an important preventive element. Yet, whilst sickness insurance on a national scale is a social service of proved value, it has not had these effects. Morbidity data available during the past few years show that incapacitating illness has tended to rise and with yearly fluctuations remains today at a new high level. This

persistence of incapacitating illness amongst the insured population at a high general level, in spite of advances in preventive and curative medicine, is indicated in the successive Annual Reports on Incapacitating Sickness in the Insured Population, published by the Department of Health for Scotland. It is a fact which deserves the serious consideration of all interested in the public welfare."

In the year 1935-1936 "the number of days of incapacity for an insured person per annum" was 11½ days, "an increase of 5 per cent over the previous year," which constituted a "new high record." (This, incidentally, is a higher figure than any of numerous "surveys" that have been conducted in the U. S. have been able to discover.) Yet the insured population excludes young children and all persons over 65 years of age. The average duration of individual sicknesses has increased from a quinquennial average, in the years 1930-1935 inclusive, of 46.66 days to 52.1 in 1935 and 1936. While the figures for 1936-1937 have not yet been published, Dr. Walker states: "I am informed that they show no evidence of any general improvement. They are, in fact, in some respects the worst noted since these data were first recorded seven years

ago." Part of this is due to an influenza epidemic but the upward trend would have continued even without this exceptional condition.

He does not apparently consider that this sickness is due only to a lack of medical attention but rather asks the question "whether further and more intensive efforts to improve environment are required in the direction of housing, reduction of overcrowding, instruction in personal hygiene, eradication of bad dietetic and other habits, etc." He also recognizes that there is a question of whether this has been due "to a real increase in incapacitating sickness" or "to an increase in payments to persons who are not, in fact, incapable of work." He notes that there was a "tremendous rise in payments in 1926 at the time of the general strike, when there were no outbreaks of epidemic disease." He also suggests that "too great a concentration by the patient on the efforts and means to cure him sometimes results in prolonging his illness." There has been an apparently great increase in psychoneurosis, although he mentions that this may possibly be due to an increased tendency among physicians to emphasize such illnesses. A test of thirty-four insulin-treated diabetic patients "showed that the facilities available for supervision and treatment were inadequate and that in the majority of cases the disease was not properly controlled" and complains that "there is a vast lag between present-day knowledge of preventive medicine and the practical application of this knowledge in family practice." Even under insurance, medical facilities "should be made use of at a relatively earlier stage in the development of illness."

CARE FOR SOCIAL SECURITY CLIENTS IN THE STATE OF WASHINGTON

The State Department of Social Security of Washington has approved a plan for medical-dental care which is based on the one previously in effect under the Federal Emergency Relief Administration and follows closely plans submitted by the Washington State Medical Association and by the State Dental Association. The plan is in line with the following resolution passed by the Washington State Association of County Commissioners in their annual meeting held in Yakima from June 24 to 26, 1937:

WHEREAS, It is the desire of the county commissioners of the state of Washington to extend the best possible medical service consistent with funds available to the people of the state of Washington who must depend on public support for such services;

WHEREAS, Our principles of American liberty and independence dictate that such service should include a free choice of physician; and

WHEREAS, The State Social Security Act provides funds for medical services and empowers the several boards of county commissioners to contract for such services; be it

Resolved, That we, the Washington State Association of County Commissioners, endorse the adoption by county boards of medical programs which provide for contracts with and between their local medical and dental profession adapted to local conditions and granting free choice of physician.

A State Medical-Dental Board has been set up "to be composed of one or more but not to exceed three representatives of the Executive Board of the State Association of County Commissioners, the State Director of Health, the State Directory of Social Security, a committee of three physicians elected or appointed by the Washington State Medical Association or its duly authorized agency, and three dentists elected or appointed by the Washington State Dental Association."

A County Medical-Dental Board has been created in each county, "to be composed of three County Commissioners, the County Health Officer, Local Administrator for Public Assistance, a committee of three physicians elected or appointed by the County Medical Society, and three dentists elected or appointed by the County Dental Society." The doctors and dentists are to be appointed by the respective county medical-dental groups and are generally to "supervise and administer the medical-dental program of its respective county." The duty is placed on the county board of undertaking "as its immediate responsibility a study of medical-dental service in the county over the past three or four years," of drawing up a plan for medical-dental care, and of recommending "an amount monthly and quarterly to cover medical-dental care."

Any licensed physician or dentist who agrees to abide by the rules and regulations shall be entitled to practice under the agreement and be subject to the free choice of the patients covered. The procedure under the plan as outlined is much like that under the FERA, except that it provides for practically all forms of medical care, including separate agreements for hospitalization. What might be called a standard fee schedule is established but it is provided that this "shall be subject to prorating in keeping with the budgeted funds avail-

Fee Schedule

| | |
|--|---------|
| First office or home visit..... | \$ 3.00 |
| Subsequent home visits..... | 2.50 |
| Subsequent office visits..... | 2.00 |
| Obstetric Care: Antepartum on per call basis but not to exceed the maximum of..... | 10.00 |
| Delivery (when in the home) including postpartum care..... | 20.00 |
| Delivery (when in the hospital or maternity home) including postpartum care..... | 10.00 |
| Fractures and dislocation cases shall be at the State Department of Labor and Industries rates. | |
| X-rays (when authorized by the Medical Executive Committee) shall be at the State Department of Labor and Industries rates. | |
| Eye examinations (refractions and subsequent check up)..... | 5.00 |
| Special physical examination or special examination by a psychiatrist in certain child welfare cases (not subject to prorating)..... | 3.00 |
| Requisition must read "special—net—not subject to prorating." | |

able for the Medical-Dental Program for the county." This fee schedule covers the items given in the accompanying table.

Special operative procedures where included shall as nearly as possible be billed to conform to the State Department of Labor and Industries fee schedule. (Subject to change and adjustment of the State Medical-Dental Board.) Only one call will be allowed regardless of the number of patients seen in a family on the same visit.

Fifty cents per mile one way from beyond the city limits will be allowed per trip irrespective of the number of homes or patients visited, except that no mileage shall be allowed on the first three miles from the city center.

Fees for all services shall be subject to the approval of the State Medical Executive Committee.

There are separate provisions for the dentists describing the character and limits of the service to be given and for a county medical-dental board to examine the work done and to authorize payment.

PAYMENT FOR PHYSICIANS' SERVICES IN OUTPATIENT DEPARTMENTS

New York physicians are seeking to obtain payment for physicians in dispensary service. The Commissioner of Hospitals, Dr. S. S. Goldwater, has agreed that dispensary physicians

Percentage of Population Treated in the Outpatient Departments of Hospitals in Greater New York

| Years | Population of Greater New York* | Number of Outpatient Department Patients† | Per Cent of Population Treated in Outpatient Department | Per Cent on 4.5 Visits |
|-----------|---------------------------------|---|---|------------------------|
| 1920..... | 5,686,249 | 927,421 | 16.3 | |
| 1929..... | 6,881,882 | 1,632,937 | 24.0 | |
| 1930..... | 7,014,649 | 1,874,750 | 26.7 | |
| 1931..... | 7,090,089 | 2,020,580 | 28.6 | 19.1 |
| 1932..... | 7,218,223 | 2,229,405 | 30.9 | 20.6 |
| 1933..... | 7,346,007 | 2,279,307 | 31.0 | 20.7 |
| 1934..... | 7,473,791 | 2,328,672 | 31.1 | 20.7 |
| 1935..... | 7,294,894§ | 2,256,631 | 32.3 | 21.5 |
| 1936..... | 7,363,624 | 2,372,866 | 32.2 | 21.5 |

* Bureau of Vital Statistics—Department of Health. In 1935 known as the Bureau of Records of the Department of Health.

† Figures do not include patients treated in dispensaries not connected with hospitals.

‡ This figure obtained by dividing the number of visits to the outpatient department by 3.

§ Estimated by a new method by the Bureau of Records adopted by the Federal Bureau of the Census.

should be paid and will incorporate the necessary amount to do this in his budget. According to the *New York Medical Week* (17:3 [Aug. 27] 1938) there is still little hope that the necessary appropriation will be made.

There has been such a steady increase in the number of persons and the percentage of the population treated in outpatient departments as to make this form of practice a formidable competitor of private practice and to constitute a heavy burden on the physicians who give their services without pay.

OFFICIAL NOTES

SCIENTIFIC EXHIBIT

Application blanks are now available for space in the Scientific Exhibit at the St. Louis Session, May 15-19, 1939. Attention is called to the fact that the meeting is a month earlier than usual, and applications close Jan. 5, 1939. Blanks will be sent on request to the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company entitled "Your Health" will begin Wednesday, October 19, and run consecutively for thirty-six weeks. The program will be broadcast over the Blue network of the National Broadcasting Company each Wednesday at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).*

These programs will be broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The programs to be broadcast in the first group, together with their dates and their topics, are as follows:

October 19. What Is Health?
October 26. Growing Strong.[†]
November 2. Seeing and Hearing Well.
November 9. Healthier Boys and Girls.

The following is a list of the stations connected with the Blue network of the National Broadcasting Company, but no assurance can be given as to how many of these stations will broadcast the program "Your Health":

| Basic Blue Network | | | | | |
|--------------------|--------------|----------|----------------------|------|-----------------|
| WJZ | New York | WEER | Buffalo | KSO | Des Moines |
| WBZ | Boston | KDKA | Pittsburgh | KOIL | Omaha |

* Owing to program conflicts, there will be no Chicago broadcast of the network program. Instead, a recording of the program will be broadcast over Station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

† Program may be cancelled; attempting to arrange an evening program.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—Dr. William Bruce Nelson, Fairfield, has been appointed health officer of Baldwin County to succeed Dr. Arthur J. Vandergrind, Bay Minette, who has accepted a commission in the U. S. Army Medical Corps.—Dr. Hugh C. McRee, formerly health officer of Lee County and recently engaged in special work under the supervision of the bureau of preventable diseases of the state department of health, has been appointed health officer of Marion County, effective September 15, succeeding Dr. Thomas L. Owings, Hamilton, resigned.

CALIFORNIA

Plague Infection.—According to *Public Health Reports*, plague infection was proved in one fisher squirrel collected July 20, 6 miles east of Seven Oaks, San Bernardino County, and in a pool of eighty-four fleas collected August 8 from fifty-two fisher squirrels from the Crestline public dump, 2 miles northeast of Crestline, San Bernardino County.

Program on Sulfanilamide.—The San Francisco County Medical Society devoted its meeting October 11 to a discussion of sulfanilamide. The speakers included Drs. Windsor C. Cutting, chemistry and pharmacology; Arthur Haim, experimental background; Arthur L. Bloomfield, use in internal medicine; Edward B. Shaw, use in pediatrics; Donald A. Dallas, use in gynecology and obstetrics, and Clark M. Johnson, use in urology.

COLORADO

Personal.—Dr. Jackson L. Sadler, Denver, assistant director of the maternal and child health division of the Colorado state board of health, has resigned to enter private practice in Fort Collins, it is reported.

Society News.—Dr. Clifford Lee Wilmoth discussed "Hepatic and Pleural-Hepatic Abscesses" before a meeting of the Medical Society of the City and County of Denver August 2. Dr. Charles Armstrong, U. S. Public Health Service, Washington, D. C., among others, addressed the society September 6 on the work of the service on epidemic encephalitis. The society was addressed October 4 by Drs. Harry Gauss on "Gastrointestinal Symptoms in Anorectal Disease" and Edward J. Meister, "Problems in Preoperative Irradiation of Carcinoma of the Heart."

FLORIDA

Regional Meeting.—The Florida East Coast Medical Association will meet in Rockledge October 28-29. Among the speakers will be:

Dr. Arthur J. Logie, Jacksonville, The Value and Significance of the Tuberculin Test.
Dr. Harold H. Fox, Miami, Oligurias with Blood Transfusions.
Dr. Fred Mathers, Orlando, Differential Diagnosis of Jaundice.
Dr. Evans B. Wood, Daytona Beach, Treatment of Coronary Occlusion.
Dr. Joseph S. Stewart, Miami, Psychological Aspect of the Diagnosis of Intestinal Obstruction.

Society News.—Drs. Efton J. Thomas, Miami Beach, and Edward W. Cullipher, Miami, addressed the Dade County Medical Society September 6 on "Jellyfish and Portuguese Man-of-War Stings" and "Common Foot Ailments" respectively.—At a meeting of the Leon-Gadsden-Liberty-Wakulla-Jefferson County Medical Society, Wakulla Springs, August 18, the speakers were Drs. Mark F. Boyd, Tallahassee, on malaria; Robert C. Pendergrass, Americus, Ga., the chronic cough, and Arthur J. Logie, Jacksonville, tuberculin tests.

GEORGIA

District Meetings.—The Fifth District Medical Society met in Atlanta October 6, with Dr. Howard M. Clute, Boston, as the guest speaker on "Diagnosis and Management of Acute Cholecystitis." Other speakers were Drs. Thomas C. Davison, Atlanta, on "Factors Influencing the Mortality of Ruptured Gastric and Duodenal Ulcers"; Grady N. Coker, Canton, "Some of Our Mistakes," and Maurice L. Blatt, Chicago, "Rabies."—The Fourth District Medical Society and the Georgia section of the Southeastern Surgical Congress held a

joint meeting at La Grange August 17. Among the speakers were Drs. Frederick J. Waas, Jacksonville, Fla., on hernia; Robert L. Sanders, Memphis, Tenn., diseases of the biliary system; Thomas P. Goodwyn, Atlanta, fracture of the neck of the femur, and Murdock S. Equen, Atlanta, acute mastoid.

ILLINOIS

Annual Branch Urologic Meeting.—The fifteenth annual meeting of the North Central Branch of the American Urological Association was held at the Pere Marquette Hotel, Peoria, September 30. The following were among the speakers:

- Dr. James T. Priestley, Rochester, Minn., Treatment of Bilateral Staghorn Renal Calculi.
- Dr. John K. Ormond, Detroit, Necrosis of Part of Kidney with Temporary Urinary Fistula Following Section of Aberrant Vessel.
- Drs. Henry O. Mertz and William E. Crump, Indianapolis, Leiomyosarcoma of the Spermatic Cord Complicated by Blood Dyscrasia: Report of Case.
- Dr. Sam W. Litzenger, Anderson, Duplication of Ureter with One Branch Ending Blindly: Case Report.
- Dr. John A. Fisher, Cincinnati, Congenital Unilateral Renal Agenesis: Brief Summary of the Literature with Reports of Two Interesting Cases.
- Dr. Seldon R. Hoover, Quincy, Ill., Prostatism in Women.
- Dr. Floyd C. Hendrickson, Canton, Ohio, Congenital Contracture of the Vesical Neck: A Report of Seven Cases.
- Dr. John H. Morrissey, New York, Treatment of Acute and Chronic Adnexal Suppuration.
- Dr. William N. Taylor, Columbus, Ohio, Mycotic Aneurysm.
- Drs. Dorris F. Rudnick and Alex B. Ragins, Chicago, Malacoplakia of Urinary Bladder.
- Drs. Henry B. Freiberg and Harry O. Lepsky, Cincinnati, Restoration of the Continuity of the Vas Deferens Eight Years After Bilateral Vasectomy.
- Dr. Gilbert J. Thomas, Minneapolis, Diagnosis and Treatment of Subacute and Chronic Lesions of Tuberculosis in the Genital Tract.
- Dr. Norris J. Heckel, Chicago, Benign Neoplasms of the Kidney with Report of a Papillary Cyst Adenoma.
- Dr. George H. Ewell, Madison, Wis., Traumatic Epididymo-orchitis.
- Dr. Harry A. Durkin, Peoria, Cardiac Care in Prostatic Surgery.
- Dr. Alf H. Gundersen, LaCrosse, Wis., Management of the Very Aged Prostatic with Report of Seventy-Five Cases of 75 Years Old with End Results.
- Dr. Clifford W. Losh, Des Moines, Iowa, Transurethral versus Suprapubic Prostatectomies.
- Dr. Victor J. LaRose, Bismarck, N. D., A Simple Apparatus for Controlling Traction on the Hemostatic Bag Catheter When Used After Transurethral Prostatic Resection.
- Dr. Charles H. McKenna, Chicago, Operative Technic of Hypospadias.
- Drs. Robert H. Herbst and James W. Merricks Jr., Chicago, Seminal Vesiculitis: A Study Carried Out by Retrograde Catheterization and Dilatation of the Ejaculatory Ducts with Visualization of the Seminal Vesicles.
- Dr. A. Jerome Sparks, Fort Wayne, Ind., Pericystitis.
- Dr. George C. Burr, Detroit, Uterovesical Fistula.
- Dr. William S. Ehrich, Evansville, Ind., Demonstration of Some Useful Urologic Gadgets.

The North Central Branch derives its membership from Iowa, North and South Dakota, Minnesota, Wisconsin, Central Canada, Illinois, Indiana, Michigan and Ohio. Dr. Charles C. Higgins, Cleveland, was elected president; Dr. Bransford L. Adelsberger, Peoria, vice president, and Dr. William J. Baker, Chicago, secretary.

Chicago

Public Health Lectures for Nurses.—The Tuberculosis Institute of Chicago and Cook County will present a series of lectures on public health and social problems for graduate nurses, to be held during the next three months. Three groups of lectures are planned to be given at the University of Illinois College of Medicine, at the University Clinics, University of Chicago, and at Grant Hospital. The following physicians will be among the speakers:

- Drs. Hugo O. Deuss and William B. Tucker, Diagnosis of Tuberculosis.
- Drs. Max Biesenthal and Jerome R. Head, Treatment of Pulmonary Tuberculosis.
- Drs. George K. Fenn, Harold C. Lueth and George V. Le Roy, Heart Disease.
- Drs. John A. Wolfer and Max Cutler, Cancer.
- Dr. Paul A. Teschner, The Place of the Nurse in the Public Health Field.
- Drs. John A. Bigler and Arthur F. Abt, Infant Welfare and the Health of the Preschool Child.
- Dr. Arthur E. Mahle, The Place of Nutrition in a Public Health Program.

INDIANA

District Health Departments Confer.—The second annual conference of the district health department personnel was held at Indiana University, Bloomington, August 22-23. Speakers included Drs. John W. Ferree, Indianapolis, chief, bureau of local health administration, state board of health, who presided; Charles K. Kincaid, New Albany; Chester A. Hicks, Huntingburg; Lewis C. Robbins, Indianapolis, who presided at the second session, and Oliver W. Greer, Indianapolis.

New Agency to Supervise State Institutions.—The state welfare department has created a new division of medical care to supervise the work of the five state mental hospitals, two institutions for the feeble-minded, a village for epileptic patients, soldiers' home and sanatorium for tuberculosis. Dr. George C. Stevens, psychiatrist for the welfare department's division of correction, has been appointed director of the new division with Dr. Lillian G. Moulton as his assistant and Miss Nelle W. Massey as a nutritionist. According to newspaper accounts, points in the new program include: four annual inspections of each institution; investigation of all accidents and sudden, unnatural or violent deaths and recommendations for prevention of such accidents; the setting up and maintaining of suitable standards of care and psychiatric treatment; establishment of nutritious, yet economical dietary standards; passing on qualifications of personnel, and supervision of laboratories. Dr. Stevens was appointed to the division of correction last May.

MASSACHUSETTS

Dr. Strong Made Professor Emeritus.—Dr. Richard P. Strong, since 1913 professor of tropical medicine at Harvard University Medical School, has retired from that professorship with the title emeritus, according to the *New York Times*. Born in Virginia in 1872, Dr. Strong received his medical degree at Johns Hopkins University School of Medicine, Baltimore, in 1897. He served in the U. S. Army Medical Corps and as president of the board for investigation of tropical diseases in the Philippine Islands from 1899 until 1901. He established and directed the work of the Army Pathological Laboratory and directed the Government Biological Laboratory, Manila, from 1901 to 1913. He resigned from the army in 1902. He was professor of tropical medicine at the College of Medicine and Surgery, University of the Philippine Islands, from 1907 to 1913, then came to Harvard. He has been a member of the Massachusetts State Health Department since 1921 and has served as president of the following: Association of American Physicians, 1925-1926; Academy of Tropical Medicine, 1936; American Society of Tropical Medicine, 1914, and American Society of Parasitologists, 1914. Dr. Strong is a member of many scientific societies and has served as delegate to the meetings of numerous international organizations. Among other posts held during the World War he was director of the department of medical research of the American Red Cross. The Distinguished Service Medal is among the many honors bestowed on Dr. Strong.

MICHIGAN

Principal Causes of Death.—According to the state medical journal, in a total of 53,468 deaths in 1937 in Michigan, 37,477 were the combined toll of heart disease, cancer, apoplexy, pneumonia, coronary disease and angina, nephritis, accidents exclusive of automobile, automobile accidents, tuberculosis and diabetes. Heart disease caused 9,726 deaths, giving a mortality rate of 190.97 per hundred thousand population and showing the largest decrease in mortality from this cause in recent years; the 1936 rate was 197.04 when 10,010 deaths occurred. A slight decrease was noted for cancer. Apoplexy replaced pneumonia as the third major cause of death. Pneumonia accounted for 4,098 deaths; nephritis, 2,931 (the lowest in ten years); accidental deaths, excluding those caused by automobiles, 2,405; automobile deaths, 2,175 (an all time high); tuberculosis, 2,119; diabetes, 1,255. There were 91,566 births in 1937 with a rate of 17.98 per thousand population, the highest since 1931. The infant mortality rate was the lowest ever recorded with the exception of 1936. A new low maternal mortality rate was established in 1937. There were 326 deaths of mothers from causes connected with pregnancy and childbirth, giving a rate of 3.56 per thousand live births.

MINNESOTA

O'Leary, Unlicensed, Jailed.—L. Leo O'Leary, aged 23, pleaded guilty August 24 to a charge of practicing healing without a basic science certificate and received a suspended sentence of one year in the Clay County Jail from Judge Anton Thompson in the district court at Moorhead. A professional card in the *Barnesville Record Review*, July 7, read:

L. Leo O'Leary
Drugless Therapy
Electro-Hydro Therapy Treatments
Dietetics and Baths
Office at Broadway Hotel
Hours 1-6 and by appointment
Phone 72

He pleaded guilty after spending eight days in the Clay County Jail. O'Leary stated that he studied at the "National College of Drugless Physicians in Chicago," and also that he

started a three months correspondence course at the Swedish College of Massage in Chicago; that he was to pay about \$30 for the course but had paid only \$3 and received a half dozen lessons. He maintained office hours only in the afternoon and devoted his mornings to the sale of aluminum ware. In suspending the sentence, the judge told O'Leary that he was to refrain from practicing healing until he was licensed, to pay his personal obligations at Barnesville on or before March 1, 1939, and to pay the court costs within sixty days.

MISSISSIPPI

Personal.—Dr. George H. Wood, Batesville, has been made health officer of Panola County on a part time basis, succeeding the late Dr. Albert P. Alexander, Como.—Dr. Evan M. Gavin, Stafford Springs, was recently elected district commander of the seventh district of the American Legion; the district comprises the counties of Clarke, Jasper, Wayne, Jones, Covington, Smith and Simpson.

NEBRASKA

Annual Mid-West Clinical Meeting.—The annual Omaha Mid-West Clinical Assembly will be presented at the Hotel Paxton October 24-28 with the following speakers:

- Dr. Robert T. Frank, New York, Treatment of Rectocele, Cystocele and Prolapse of the Uterus; Treatment of Functional Diseases.
- Dr. Heyworth N. Sanford, Chicago, Hemorrhagic Diseases of Infancy and Childhood; Cerebral Hemorrhage of the New-Born.
- Dr. Foster Kennedy, New York, The Organic Background of Mind; Epilepsy; Insanity as a Defense in Crime.
- Dr. Henry L. Bockus, Philadelphia, Practical Application of Recent Advances in Our Knowledge of Liver Function; Diagnosis and Treatment of Chronic Gastritis.
- Dr. Cameron Haight, Ann Arbor, Mich., Practical Considerations Relating to Acute and Chronic Empyema; Diagnosis and Management of Carcinoma of the Lung.
- Dr. Oliver H. Perry Pepper, Philadelphia, Principles of Diagnosis and Treatment of Disease in the Elderly; Recognition and Treatment of Anemia Due to Increased Blood Destruction.
- Dr. Gordon B. New, Rochester, Minn., Diagnosis of Laryngeal Lesions; Deformities of the Face Corrected by Plastic Surgery.
- Dr. Edward L. Jenkinson, Chicago, Value of Repeated Cholecystography and the Effect of Medical Management on the Visualization of the Gallbladder; Roentgen Examination of the Small Bowel.
- Dr. Alfred R. Shands Jr., Wilmington, Del., Osteomyelitis in Children; Post-Poliomyelitis Problems.
- Dr. Oliver S. Ormsby, Chicago, Precancerous Dermatoses; Contact Dermatitis.
- Dr. Louis J. Hirschman, Detroit, The Rationale of Internal Hemorrhoidectomy; The Two-Stage Operation for Anal Fistula.
- Dr. Ralph M. Waters, Madison, Wis., Development of Anesthesiology.
- Dr. John S. Lundy, Rochester, Minn., Indications for Rectal, Intravenous, Spinal and Regional Anesthesia.
- Dr. Kenneth C. McCarthy, Toledo, Ohio, Anesthesia for Bad Risk Patients.

A symposium on anesthesia will be presented by Drs. Archibald R. McIntyre, Omaha, and Robert Maxwell Grier, Evanston, Ill. Clinics will be held every afternoon.

NEW MEXICO

First Evidence of Plague Infection.—The U. S. Public Health Service reported August 20 that plague infection had been proved in prairie dogs, in pools of fleas from prairie dogs and field mice in Catron County. This is believed to be the first evidence of the existence of plague in the state.

NEW YORK

District Meeting.—The Third District Branch of the Medical Society of the State of New York held its annual meeting at Cobleskill September 20 with the following program:

- Dr. Frederick A. D. Alexander, Albany, Modern Anesthesia.
- Dr. Morris A. Goldberger, New York, Modern Trends in Obstetric Practice.
- Dr. Thomas Wood Clarke, Utica, Allergic Manifestations in the Central Nervous System.
- Dr. Donald Guthrie, Sayre, Pa., Diagnosis and Treatment of Hyperthyroidism.
- Dr. Louis K. Diamond, Boston, Anemia in Children.
- Dr. Charles G. Heyd, New York, Diagnostic Interpretation of Jaundice.

Examination of Food Handlers Believed Ineffective.—The New York State Association of Public Health Laboratories recently adopted a resolution declaring that routine laboratory examinations of food handlers, milk handlers and domestic servants are ineffective as a protection of the public health and approving repeal of any existent legislation or mandatory regulation requiring such tests as routine. The resolution pointed out that many public health authorities have seriously questioned the value of such examinations and that when results are negative a false sense of security may be engendered. It also suggested that the performance of the tests requires financial outlay with no commensurate return to public health.

New York City

Manson-Bahr Lectures on Dysentery.—Dr. Philip E. C. Manson-Bahr, School of Tropical Medicine, London, conducted a clinic on bacillary dysentery September 30 for students and guests of the Long Island College of Medicine. A case of proved *Shigella dysenteriae* infection in a seaman from Calcutta was presented from the tropical disease service of the Long Island College Hospital. After discussion of the case Dr. Manson-Bahr spoke on dysentery, illustrating his talk with epidiascope projections of his collection of original drawings.

Society News.—Drs. Foster Kennedy and Elizabeth I. Adamson addressed the Medical Society of the County of Queens, September 27, on "The Organic Background of Mind" and "Mild Depressions Cared for by the Family Doctor" respectively. The society will present a series of lectures on skin disease November 14-17, with the following lecturers: Drs. Ida J. Mintzer, Jamaica, on "Common Skin Conditions"; Charles S. Miller, "New Growths of the Skin"; Joel Schweig, "Parasitic Diseases of the Skin" and Rudolph Boenke, "Therapeutics of Common Skin Diseases."—Dr. Arthur W. Grace gave a Friday afternoon lecture before the Medical Society of the County of Kings, Brooklyn, October 7, on "Lymphogranuloma Venereum"; Dr. William S. Collens spoke October 14 on "Diagnostic and Therapeutic Aspects of Peripheral Diseases."—A symposium on "The Future of American Medicine" will be held in the grand ballroom of the Hotel Center October 21 under the auspices of the Interne Council of America. The two principal speakers will be Drs. John P. Peters, professor of medicine, Yale University School of Medicine, New Haven, Conn., and Philip I. Nash, president-elect of the Medical Society of the County of Kings.

NORTH CAROLINA

Professor Appointed.—Dr. John W. Roy Norton, assistant director of preventive medicine, state board of health, Raleigh, has been appointed professor of public health administration in the division of public health, University of North Carolina School of Medicine, Chapel Hill. Dr. Norton graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1928 and was for several years health officer of Rocky Mount before joining the state board of health.

OHIO

Personal.—Dr. Rollin D. Worden, Ravenna, resigned September 1 as health commissioner of Portage County. Dr. Percy L. Harris, Columbus, now a member of the staff of the state health department, succeeds Dr. Worden.—Dr. Carl J. Wiggers, professor of physiology, Western Reserve University School of Medicine, Cleveland, sailed September 9 for South America to give a series of lectures in Chile and Argentina.

Society News.—Dr. Edward William Alton Ochsnor, New Orleans, addressed the Academy of Medicine of Cleveland September 16 on "Management of Peripheral Vascular Disease."—Mr. R. H. Nesbitt, Akron lawyer, addressed the Summit County Medical Society, Akron, September 6, on "The Doctor and the Law."—Dr. Perrin H. Long, Baltimore, addressed the Mahoning County Medical Society, Youngstown, September 20, on sulfanilamide.

District Meeting.—The Fifth District Medical Society will meet at the Medical Library Auditorium in Cleveland October 21 to hear the following program:

- Dr. Arthur D. Nichol, Clinical Observations on the Hyperactive Carotid Sinus.
- Dr. Abraham Strauss, The Management of Undescended Testes with Demonstration of Cases.
- Dr. Edmund E. Beard, Endocrine Aspects of Pituitary Tumors.
- Dr. Gerald S. Shibley, Treatment of Pneumonia.
- Dr. John A. Toomey, Treatment of the Meningitides.
- Dr. Curtis F. Garvin, The Dangers of Sulfanilamide Therapy.
- Dr. Raymond C. McKay, Early Diagnosis and Treatment of Pulmonary Tuberculosis.
- Dr. Edward E. Goldman, A Simple Test for Determining the Presence of Gastrointestinal Lesions.
- Dr. Thomas E. Jones, Treatment of Carcinoma of the Rectum.

The general meeting in the evening will be under the auspices of the Academy of Medicine of Cleveland with Dr. Clifford J. Barborka, Chicago, speaking on "The Management of Nutritional Diseases." Drs. Hubert C. King and Barney J. Hein, Toledo, presidents respectively of the academy and the state medical association, will also speak.

OKLAHOMA

New Health Officers.—Dr. Ferdinand R. Hassler Jr., formerly of Oklahoma City, has been appointed director of a new city and county health unit in Muskogee and Muskogee County.—Dr. James O. Hood, Norman, has been appointed health officer of Cleveland County to succeed Dr. Guy H. Williams.

OREGON

Hospital News.—The Dr. Robert C. Coffey Clinic and Hospital, Portland, will henceforth be known as the Coffey Memorial Hospital in memory of Dr. Coffey, who was killed in an airplane accident Nov. 9, 1933.—A new \$250,000 hospital with forty-three beds has been completed at La Grande; it will be known as St. Joseph's Hospital.

New Buildings for the University.—A laboratory building and a library with an auditorium are to be built immediately at the University of Oregon Medical School, Portland, it was announced September 10, when a PWA grant of \$163,000 was approved. This grant augments a gift of \$100,000 from Dr. John E. Weeks, retired physician of Portland, and a grant of \$100,000 from the Rockefeller Foundation. Plans call for a library building of reinforced concrete, containing an auditorium, track rooms, reading rooms, study rooms and a lobby. It will be connected by a passage with the three story laboratory building, which will be an extension of the west wing of the medical school. The library contains about 30,000 volumes.

PENNSYLVANIA

Annual Seminar.—The ninth annual postgraduate seminar will be presented at the Easton Hospital, Easton, October 26. The speakers will be:

- Dr. John de J. Pemberton, Rochester, Minn., Surgery of Diseases Associated with Splenomegaly.
- Dr. William Halsey Barker, Baltimore, Clinical Use of Sulfanilamide.
- Dr. Frank C. Hamm, Brooklyn, Kidney Conditions in Children.
- Dr. Harrison F. Flippin, Philadelphia, Undulant Fever.
- Dr. Thomas T. Mackie, New York, Pathological Histology and Amebic Colitis.
- Dr. Lewis K. Ferguson, Philadelphia, Newer Methods in the Management of the Surgical Ambulatory Patient.

Philadelphia

Hospital Lectures.—Mount Sinai Hospital opened its seventh annual series of health talks for the public September 21 with a talk by Dr. Samuel E. Rynes entitled "How Many People Are Allergic?" Dr. Sigmund S. Greenbaum will speak October 19 on "Cosmetics and Skin Health" and Dr. Theodore H. Mendell, November 16, on "High Blood Pressure—The Threat to Long Life."

Society News.—Drs. Rudolf L. Roddy, James S. Forrester and Harold Landow addressed the Obstetrical Society of Philadelphia October 6 on "Management of an Institutional Outbreak of Infectious Diarrhea of the Newborn" and Dr. Richard Manges Smith, "X-Ray Localization of the Placenta by Soft Tissue Technic and Without the Use of Opaque Media."—At a meeting of the Philadelphia Academy of Surgery October 10 the speakers were Drs. Isidor S. Ravdin, Harry E. Knox and Calvin M. Smyth Jr., on "The Problems of Acute Appendicitis with Peritonitis" and Ernest G. Williamson and Lynn M. Rankin, "Management of Appendicitis Complicated by Peritonitis with Special Reference to Postural Drainage."

TENNESSEE

Personal.—Dr. David M. Cowgill, Madisonville, health officer of Monroe County, has been appointed director of the Giles County health unit. He succeeds Dr. J. W. Erwin, Pulaski, who has been appointed in Washington County.

University News.—Miss Frances Helen Zeigler, R.N., dean of the school of nursing and director of nursing service at the Medical College of Virginia, Richmond, has been appointed dean of the school of nursing at Vanderbilt University, Nashville.

Society News.—Drs. Conley H. Sanford and Neuton S. Stern, Memphis, addressed the Madison County Medical Society, Jackson, September 6, on "Medical Management of Gallbladder Disease" and "Coronary Sclerosis, Angina Pectoris and Coronary Occlusion" respectively.—Dr. Frank H. Booher, Lynchburg, addressed the Bedford County Medical Society July 21 in Shelbyville on meningitis.

TEXAS

Dates Set for Clinical Conference.—The Dallas Southern Clinical Society announces that the eleventh annual spring conference will be held March 13-16 at the Hotel Adolphus. The guest speakers will be Drs. Fuller Albright, Richard B. Cattell, Charles F. McKhann, Boston; Sanford R. Gifford, Robert H. Herbst and Harry E. Mock, Chicago; Louis J. Karnosh, Cleveland; Dean M. Lierle, Iowa City; William S. Middleton, Madison, Wis.; Alfred C. Reed, San Francisco; Wendell G. Scott, St. Louis, and Richard W. Telinde, Baltimore. Dr. George A. Schenewerk is secretary of the society.

Post Graduate Assembly in Houston.—The seventh Post Graduate Medical Assembly of South Texas will be held at the Rice Hotel, Houston, November 1-3, with the following guest speakers:

- Dr. Francis Heed Adler, professor of ophthalmology, University of Pennsylvania School of Medicine, Philadelphia.
- Dr. Fremont A. Chandler, assistant professor of orthopedic surgery, Northwestern University Medical School, Chicago.
- Dr. Carey Culbertson, clinical professor of obstetrics and gynecology, Rush Medical College, Chicago.
- Dr. Louis J. Hirschman, professor of proctology, Wayne University College of Medicine, Detroit.
- Dr. Robert Louis Levy, professor of clinical medicine, College of Physicians and Surgeons, Columbia University, New York.
- Dr. Thomas T. Mackie, New York.
- Dr. Harvey B. Matthews, clinical professor of obstetrics and gynecology, Long Island College of Medicine, Brooklyn.
- Dr. Henry G. Poncher, associate professor of pediatrics, University of Illinois College of Medicine, Chicago.
- Dr. Mont R. Reid, professor of surgery, University of Cincinnati College of Medicine, Cincinnati.
- Dr. Lyman G. Richards, associate professor of otolaryngology, Tufts College Medical School, Boston.
- Dr. John J. Shea, Memphis, Tenn.
- Dr. Edward H. Skinner, Kansas City, Mo.
- Dr. Gilbert J. Thomas, clinical associate professor of urology, University of Minnesota Medical School, Minneapolis.
- Dr. Derrick T. Vail Jr., professor of ophthalmology, University of Cincinnati College of Medicine, Cincinnati.
- Dr. Carroll S. Wright, professor of dermatology and syphilology, Temple University School of Medicine, Philadelphia.

Meetings will be in general sessions, except for one section on diseases of the eye, ear, nose and throat. An innovation this year will be question and answer periods. There will be scientific and technical exhibits and motion pictures each day.

VIRGINIA

Society News.—At a meeting of the Southside Virginia Medical Association, Burkeville, September 13, the speakers included Drs. Thomas F. Wheeldon, Richmond, on "The Use of Metal Tubes in Osteomyelitis"; John A. Proffitt, Burkeville, "Pleural Effusions" and Wellford C. Reed, Richmond, "Significance and Management of Ankle Edema."—Richmond physicians addressed the quarterly meeting of the Mid-Tidewater Medical Society in Gloucester July 27, as follows: Drs. John L. Tabb Jr., on "X-Ray Treatment of Sinusitis"; William L. Peple, "Clinical Classification and Treatment of Cancer of the Cervix"; James H. Smith, "Abnormalities of the Thyroid" and Donald M. Faulkner, "Treatment of Fracture of the Hip with the Nail."

Testimonial to Dr. McGuire.—The Richmond Academy of Medicine gave an informal testimonial dinner in honor of Dr. Stuart McGuire September 27 at the Commonwealth Club, Richmond, in appreciation of his interest in and devotion to the academy. Dr. Austin I. Dodson, president of the academy, introduced Dr. John Shelton Horsley, chairman of the dinner committee, who presented the toastmaster, Frederic W. Boatwright, LL.D., president of the University of Richmond. Dr. John M. T. Finney, emeritus professor of surgery, Johns Hopkins University School of Medicine, Baltimore, was the chief speaker. A portrait of Dr. McGuire was presented to the academy on behalf of a group of donors by Dr. Roshier W. Miller and Dr. McGuire received a portfolio of letters. Dr. McGuire, who is 71 years old, graduated from the University of Virginia in 1891. He is emeritus professor of surgery at the Medical College of Virginia, of which he also served as president from 1914 to 1925. He was president of the Medical Society of Virginia in 1908.

WASHINGTON

Hospital News.—A new \$126,000 dispensary was placed in service at the Puget Sound Navy Yard, Bremerton, in August.—St. Martin's Hospital, a new \$50,000 institution at Tonasket, Wash., was dedicated August 25 by the Bishop of Spokane.

Society News.—Dr. Walter L. Palmer, Chicago, addressed the Spokane County Medical Society, Spokane, September 8, on "Treatment of Benign Conditions of the Gastrointestinal Tract."—Dr. Donald A. Murray, Seattle, addressed the King County Medical Society, Seattle, September 19, on "Fractured Hips Treated by Smith-Petersen Nails."

WISCONSIN

Personal.—Dr. Mina B. Glasier, Bloomington, recently resigned as a member of the state board of health after fourteen years of service. She served as president of the board in 1935 and as vice president in 1937.—Dr. Mynie G. Peterman, Milwaukee, has resigned as professor of pediatrics at the Marquette University School of Medicine, effective September 1. He was appointed in 1928.

PUERTO RICO

Hospital News.—It is reported that Dr. Thomas D. Slagle, Coamo, has been appointed superintendent of St. Luke's Memorial Hospital, Ponce, a sixty-five bed hospital supported by the Episcopal Church. Dr. Slagle, a native of North Carolina, graduated from Cornell University Medical School, New York, in 1932.

GENERAL

Society Seeks Information on Eye Hazards.—The National Society for the Prevention of Blindness requests information on industrial or occupational eye hazards for a new edition of "Eye Hazards in Industrial Occupation." The request specifies: (1) information concerning new industrial or occupational eye hazards—both accident and disease hazards; (2) recent and significant statistics concerning any occupational hazards to sight, showing frequency, severity, causes, nature of injury, degree of impairment, cost, etc.; (3) photographs showing either hazards to sight or protection against such hazards, and (4) information concerning successful methods of eliminating, counteracting or alleviating the disease and accident hazards to eyes. The society's headquarters are at 50 West Fiftieth Street, New York.

Association of American Medical Colleges.—The forty-ninth annual meeting of the Association of American Medical Colleges will be held in Syracuse, N. Y., October 24-26 under the presidency of Dr. Alan M. Chesney, Baltimore. The speakers will include:

Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., Future of the Public Health Movement.
Dr. Reginald Fitz, Boston, When and How Shall Interns Be Appointed?
Dr. Edward C. Hughes, Syracuse, Use of the Home Delivery Service in Syracuse in the Teaching of Obstetrics.
Dr. Joseph Earle Moore, Baltimore, Teaching of Syphilis.

There will also be a symposium on "The Place of Preventive Medicine in the Medical Curriculum," presented by Drs. John G. Fitzgerald, Toronto; Waller S. Leathers, Nashville, Tenn.; Frederick F. Russell, Boston, and Harry S. Mustard, New York.

American Public Health Association.—The sixty-seventh annual meeting of the American Public Health Association will be held in Kansas City October 25-28. Among numerous speakers who will address section meetings are:

Dr. George C. Ruhland, Washington, D. C., The Objectives of Health Departments.
Dr. Philip C. Jeans, Iowa City, Nutritional Requirements During Growth.
Drs. Thomas B. Turner, Baltimore; Abraham L. Gelperin, Cincinnati, and James R. Enright, Honolulu, Hawaii, Results of Contact Investigation in Syphilis in an Urban Community.
Dr. George McL. Lawson, Charlottesville, Va., Immunity Studies in Pertussis.
Dr. Thomas F. Sellers, Atlanta, Ga., Laboratory Diagnosis of Rabies.
Reuben L. Kahn, Sc.D., Ann Arbor, Mich., Fifteen Years of the Standard Kahn Test.
Franklin C. Bing, Ph.D., secretary, Council on Foods, American Medical Association, Chicago, Advances in Our Knowledge of Nutrition.
Harry B. Meller, managing director, Air Hygiene Foundation of America, Pittsburgh, Practical Procedures and Limitations in Present-Day Smoke Abatement.
Dr. Paul A. Teschner, assistant director, Bureau of Health Education, Chicago, The Doctor Looks at the Voluntary Health Agency.

Dr. Arthur T. McCormack, Louisville, Ky., president of the association, will make his official address at a general session and Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., will speak at another. Among symposiums will be those on industrial hygiene administration, venereal disease control, outposts of research and new facts for the health educator. A number of other organizations will hold meetings during the week, including the American School Health Association, the Association of Women in Public Health, the American Association of State Registration Executives and International Society of Medical Health Officers.

Research Council on Problems of Alcohol.—The American Association for the Advancement of Science has announced the appointment of the Research Council on Problems of Alcohol to make a scientific investigation of the problems related to the control of alcoholic beverages. Dr. Karl M. Bowman, director of the division of psychiatry, Bellevue Hospital, and professor of psychiatry, New York University College of Medicine, is chairman of an executive committee of fifteen members of which ten are required to be scientists. Hans T. Clarke, D.Sc., professor of biochemistry, Columbia University, is chairman of the scientific committee and Willard E. Givens,

executive secretary of the National Education Association, has been elected chairman of the educational committee. Mr. Harry H. Moore, formerly director of the Committee on Costs of Medical Care, has been chosen director of the council's activities with headquarters in New York. The primary objective of the council is to develop the sociologic and biologic facts paramount in the control of alcoholic beverages and secondly to make them available to the public. In outlining its program of research, the council will take into account other adequate studies in the field which have already been conducted, which may be contemplated and which may be under way, and it will assign each of its own studies, so far as practicable, to other research agencies, such as universities, hospitals and professional organizations. Finally, it will constantly seek to integrate the results of all studies for the purpose of resolving contradictions, of filling gaps in existing knowledge and of making available a reasonably complete and well organized body of factual data.

Changes in Status of Licensure.—The board of medical examiners of Maryland recently reported the following action:

Dr. Paul F. Wiest, Charlestown, W. Va., license suspended July 7 on his conviction of violation of the Harrison Narcotic Act.

The Minnesota State Board of Medical Examiners reports the following action:

Dr. Harold Rees, Ogilvie, Minn., license revoked May 13 for "habitual indulgence in the use of narcotics."

The Virginia state board of medical examiners reports the following:

Dr. Calvin Howard Cain, Orange, license revoked June 22 for violation of the federal narcotic laws.

Dr. Robert Scott Fitzgerald, Richmond, license revoked June 22 on account of conviction of performing an illegal operation.

The Arizona State Board of Medical Examiners announces the following:

Dr. Nathaniel D. Hightower, Phoenix, license restored July 6; placed on probation for five years and as long as a resident of Arizona to be without narcotic permit.

Dr. Richard McClellan Francis, Flagstaff, license restored July 6; placed on probation for five years and as long as a resident of Arizona to be without narcotic permit.

The Wisconsin State Board of Medical Examiners reports the following action:

Dr. Raymond James Henderson, Tomahawk, license revoked July 1 for having performed illegal operations.

CANADA

Personal.—Dr. John W. McIntosh, medical officer of health of Vancouver, B. C., retired from that position September 30.

—Dr. Pio H. Laporte, Edmundston, has been appointed minister of health and labor in the government of New Brunswick.—Dr. Randolph J. Gibbons, formerly assistant to the director of the Connaught Laboratories, University of British Columbia, Vancouver, has been appointed chief bacteriologist to the laboratory of hygiene, department of pensions and national health.

FOREIGN

Institute of Hematology in Paris.—A center for blood transfusion was opened at Saint Antoine Hospital in Paris in June, gift of Madame Deutsch de la Meurthe, a Paris philanthropist. The institute of hematology consists of four divisions: the central services where donors are registered and where requests are received; a library on hematology; a laboratory for work in connection with current needs, and a laboratory for research in hematology, including a study of preserved blood.

Personal.—Sir Arthur Newsholme, Worthing, England, received the Jenner Medal of the Royal Society of Medicine "for distinguished work in epidemiologic research or for pre-eminence in the prevention and control of epidemic disease," according to *Science*.—Mr. Wilfred B. L. Trotter, director of the surgical unit at the University College Hospital, London, has received the gold medal of the Royal Society of Medicine, awarded triennially to a "scientist, man or woman, who has made valuable contributions to the science and art of medicine."—Dr. James L. Maxwell, Shanghai, China, former editor of the *Chinese Medical Journal*, has been made a Commander of the Order of the British Empire.—At the recent meeting of the British Medical Association the Sir Charles Hastings clinical prize was presented to Dr. John W. McFeeters, according to *Science*.—The Dr. Jessie MacGregor prize in medical science of the Royal College of Physicians of Edinburgh has been awarded to Dr. Susanne J. Paterson for her work on the therapeutic uses of progesterone.

Sept. 24, 1938.

The Control of Smallpox

The minister of health has issued a memorandum on smallpox in which he draws the attention of local authorities to the possibility of preventing or limiting the spread of the disease by prompt and vigorous action. A recent survey of the world distribution of smallpox shows that the strains in different countries are of different degrees of virulence and breed true over a long series of years. In India, the Far East and Northern Africa, the prevailing strain is virulent, producing variola major, while in England, Canada, the United States, the West Indies, Brazil and South Africa, the strain is nonvirulent, producing variola minor, known also as alastrim or amas. In some of these countries the importation of the virulent strain showed the great difference between the two forms of the disease. In England the years 1920 and 1921 marked the disappearance of variola major as a serious administrative problem and the rise of variola minor to epidemic proportions. In 1917 the number of notifications of smallpox in England and Wales fell to seven; it then rose until 1927, when it reached 14,767, after which it steadily declined. In 1920 nearly all the cases were of variola minor, although outbreaks of variola major arose from the importation from abroad of a case of this form. In 1936 all the reported cases were of variola major, which in some instances was certainly, and in others probably, imported from abroad. Prompt action by the local authorities rapidly brought the outbreaks under control. Variola major has proved easier to check than variola minor, because people are alarmed by the more virulent condition and are willing to submit to all the methods of control. The international conditions in force, the vigilance of the port health authorities and the cooperation of the public have much reduced the risk of variola major reaching epidemic proportions in this country.

Variola minor is more difficult to control because its mildness leads to an attack's being unrecognized or recognized too late for exposed persons to receive the protection of vaccination. Also when persons begin to notice the mildness of the disease and that it does not kill or disfigure they are less disposed to submit to vaccination. Finally, the absence of alarm, or its subsidence, increases the difficulty of making inquiries and tracing persons who have been exposed to infection. The prominence given to cases of vaccinal encephalitis, rare though these are, also has discouraged vaccination, even after exposure to infection. Hence in spite of great efforts and much expenditure, variola minor has smoldered in some parts of the country.

The following procedure has been laid down by the minister of health: 1. The health officer should visit the patient with the physician in attendance. If smallpox is found the patient should at once be removed to the smallpox hospital. 2. The health officer should forthwith report to the ministry. 3. Vaccination or revaccination should be offered to exposed persons, and it should be kept in mind that the incubation period is to be taken as twelve days, or fourteen days to the characteristic focal rash; that if this period is divided into three intervals of seven, three and four days, successful vaccination in the first will prevent the attack, in the second will modify the eruption and in the third will have no influence; that the pertinent date is, however, not when vaccination is performed but when the reaction begins; that if the reaction, which should be manifest on the third or fourth day, is delayed by any cause, the rise of immunity is deferred, and that prevention can therefore be secured only by vaccination within a day or two of exposure. 4. Exposed persons should be kept under observation for sixteen

days after the last exposure to infection, but it is seldom necessary or desirable to isolate them in their homes. 5. The health officer should at once inform the public vaccinators so as to secure prompt vaccination of persons willing to be protected. 6. The infected house, its contents and the clothing of all who have been in close contact with the patient should be disinfected. 7. All persons with doubtful attacks should be seen at once by the health officer, and to this end physicians in the district should be notified of the presence of smallpox. 8. The health officer should notify the health officers of adjoining areas. 9. To ascertain the source of infection, careful inquiry should be made concerning the movements of the patient in the three weeks preceding the attack, particularly on the twelfth and fourteenth days prior to the onset.

Revision of Medical Standards for the Navy

The need for obtaining more men for the navy and army has led to some revision of the high standard of physical fitness which has been maintained. The standard for the navy is so high that only 25 per cent of the applicants are accepted. Only some slight relaxation has now been introduced. Except in certain branches, such as the seamen and signal branches, the men may now wear glasses to enable them to carry out their duties if they are medically fit in other respects, each case being considered on its merits by the commanding officer. For men who require spectacles when antigas respirators are worn, the side pieces are to be flattened so as to prevent leakage and the fit of all such frames is to be tested in a gas chamber. As a temporary expedient the dental standard of men who are fit in other respects and who are willing to receive treatment to render them fit for general service has been modified. Artificers and artisans for direct entry are not to be rejected for dental defects which can be remedied by treatment, which will include the free supply of dentures. Candidates for the rating of ordinary seamen who are wearing a satisfactory denture may be accepted, provided any natural teeth present are sound or readily conservable. In other ratings men who are below the normal dental standard only by loss of one pair of opposing molars may be accepted.

Casualties of Air Raids

The ministry of health has made rapid progress in organizing hospital accommodations to meet any emergency that may arise from air raids. In August the hospital authorities were told that in the event of a raid they would be expected to empty as many beds as possible by sending home patients fit to go. It is estimated that most hospitals could clear from 30 to 50 per cent of their beds in this way. The great majority of patients going home would be sitting or walking patients, and hospitals have been asked to arrange for their transport by voluntary organizations. Once at home, the patient would come under the general arrangements for evacuation of his district. Simultaneously certain hospitals, for the most part the larger general ones in the more congested areas, would "decant" patients fit to be moved, though not yet to go home, to other institutions capable of continuing their treatment but less useful for receiving air raid casualties. In the London area thirty-four hospitals have already been designated for decanting, and plans have been prepared for removing between 3,000 and 4,000 patients by ambulance trains to towns 50 miles or more from London. They would be conveyed to the railway stations by motor coaches converted to carry stretchers. Conferences have been held with all the representatives of the voluntary and municipal hospitals and with the health officers in the counties around London. Arrangements have been made in the towns which will receive patients from London for meeting the ambulance trains and conveying the patients to the hospital. The London County Council is providing surgical equipment at some of its larger hospitals not at present used for surgical cases, so that they can deal with casualties. So far the plans have been concerned principally with the utilization of existing accom-

modations, but the ministry of health has also taken steps for the acquisition of additional equipment, which will be distributed to different centers. Information has also been collected about the stocks of bedsteads, bedding and other equipment held by the trade in the various towns.

Sulphanilamide Added to the Poisons List

Sulphanilamide has been added to the official poisons list as a substance which may be supplied by pharmacists only on the written prescription of a physician, dentist or veterinary surgeon and is thus brought under the restrictions that apply to amidopyrine, barbituric acid, dinitrocresol and sulphonal. Hitherto its sale has been unrestricted. This regulation will apply not only to sulphanilamide but to related substances sold under the names of Colsulanyde, P. A. B. S., Prontosil Album, Prontosil Rubrum, Prontosil Soluble, Streptocide, Sulphonamide Emulsion, Proseptasine, Roidlone, Rubiazol and Uliron. The calamity by which seventy-three persons lost their lives in the United States by taking a preparation known as elixir of sulfanilamide has no doubt influenced the Poisons Board in its decision.

Prison for Driver Suffering from Paralysis

Almost the only condition of a driver of an automobile which gives rise to prosecution is alcoholism. A driver, aged 38, who killed a cyclist has been found guilty of manslaughter, sentenced to twelve months' imprisonment and disqualified for life from holding a driving license. When he was arrested his symptoms suggested alcoholism, but he was found to be suffering from "creeping paralysis." When asked how he applied his brake he said that, owing to his condition, he used his hand to assist his leg. He had suffered from trench fever in the war, for which he was awarded a pension, and the police gave him an excellent character.

Code of Ethics for Pharmacists

At the conference of the British Pharmaceutical Society in Edinburgh a code of ethics for pharmacists was discussed and approved. Among other provisions of the code, it is laid down that if a dispenser detects an error in a physician's prescription it is his duty to protect both the customer and the reputation of the physician by conferring confidentially with the latter. The code forbids pharmacists to discuss with patients the composition of medicine and enjoins on them that every precaution be taken to safeguard the public from poisons and all habit-forming drugs and to use no exaggerated claims for medicines.

PARIS

Sept. 17, 1938.

Incidence of Pulmonary Tuberculosis in Miners

At the July 5 meeting of the Académie de médecine of Paris, the results of a study of the incidence of pulmonary tuberculosis in miners from 1923 to 1937 in the Saint-Etienne region were reported by Drs. Crozier and Martin. They said that there were very few recent statistics available. In most articles the statement is made that the incidence is about the same for miners as for other persons. The authors were also of this opinion until they had occasion to observe a large number of cases of pulmonary tuberculosis in a hospital owned by a large coal mining company. At times nearly half of the patients had pulmonary tuberculosis, and the average was one third of the hospital capacity. Between 1923 and 1937, 23.6 per cent of the hospital deaths were due to pulmonary tuberculosis, whereas the percentage for men of the same age who were not coal miners was only 16.5. The mortality rate for all males of the Saint-Etienne region who were not engaged in coal mining during 1936, the only year for which statistics are available, was 2.4 per thousand, as compared to 3.4 per thousand for coal miners. These statistics are surprising because, as a rule, coal miners

are in the best possible condition, a complete physical examination being obligatory before they are employed. The authors attempted to explain the relatively high incidence of pulmonary tuberculosis in coal miners by the fact that, first, most of the miners come from the country and fail to become adapted to city life; second, that alcoholism and poor living conditions play an important part, and, finally, that the dust-laden atmosphere and the necessity of working in a narrow space are important predisposing causes. As prophylactic measures, the authors had suggested better housing conditions, more adequate ventilation of mines, and the calling of attention to the dangers of alcoholism. Since these measures have been employed, an encouraging decrease in the mortality rate for pulmonary tuberculosis has been noted.

The Use of Virus Vaccine Against Plague

The use of living plague bacilli (*Pasteurella pestis*), as a prophylactic measure has been given a three year trial in the large French colony of Madagascar. The results of this vaccination were submitted in a paper read by Drs. G. Girard and J. Robic at the July 5 meeting of the Académie de médecine of Paris. In 1921 there were only 187 cases of plague, but in 1935 the number rose to 3,493. As a result of intensive use of the virus vaccine, the number of cases dropped to 2,006 in 1936 and to 918 in 1937. This recession is still more marked so far (first five months) in 1938. The number of vaccinated and revaccinated persons has passed 2,000,000. The results have been infinitely better since living vaccines have been used. The mortality rate has been lowered by 80 per cent. As long as it is impossible to eliminate the animal reservoir of the bacillus, it will be necessary to continue to vaccinate every native.

Persistence of Virulence of Cholera Vibrio

It is generally admitted that the resistance of the cholera vibrio to heat and desiccation is not great. The slight resistance of the cholera spirillum, especially its sensitiveness to drying, explains the rapid and complete disappearance of cholera in once infected localities and also the fact that the disease is rarely transmitted by aerial infection. In a paper read at the July 5 meeting of the Académie de médecine of Paris by Jean Laigret and Mme. P. Auburtin, the results are reported of a recent study as to whether the cholera vibrio is as sensitive to heat and desiccation as was hitherto believed. Laigret, in collaboration with Roger Durand, had previously shown that under certain conditions the bacillus of plague can be dried without destroying its vitality. Laigret and Auburtin have since found that the cholera vibrio also can be viable after desiccation. They utilized four strains which are used in Indo-China and China in the preparation of an anticholera vaccine. The desiccation technic was that employed by the Pasteur Institute of Tunis in the preparation of the living virus vaccines against yellow fever and typhus. When the desiccated cholera vibriones were inoculated on various mediums at various intervals they showed an active growth as late as thirty-two days after desiccation. This discovery is of great importance from the standpoint of epidemiology. In all countries where cholera is endemic and there are dry and wet seasons, it has been noticed that the earliest attacks always appear after the first rain. Hitherto some native or foreign carrier has been blamed, but in view of this research by Laigret and Auburtin, the question arises whether this is true in all cases, although the natural methods of desiccation in all probability can act so as to keep the cholera vibrio alive longer than is possible so far in laboratory work. The virus of typhus, as has been shown by Nicolle for dried excreta and by Georges Blanc for lice, can remain virulent for months. The desiccation of the cholera vibrio under natural conditions and its recrudescence when in contact with water may serve to explain the annual recurrence of epidemics in countries where there are dry and wet seasons.

BERLIN

(From Our Regular Correspondent)

Sept. 3, 1938.

Congress of Public Health Physicians

Before the Congress of Public Health Physicians, in which all important interested officials of the national government were represented, Dr. Gütt, ministerial director from the national ministry of the interior, submitted an interesting report on the general state of public health. In recent years the agencies which protect the public health have been reorganized. There are today in Germany (exclusive of Austria) 753 health bureaus and 200 auxiliary centers. With these bureaus are affiliated ninety-five special departments of eugenics and racial hygiene. Full time employees of the public health services number 10,695, this number including the physicians and their trained and untrained assistants. There are 12,373 part time employees. Similar bureaus and centers are being established in Austria.

Dr. Gütt stressed the fact that leprosy, cholera, plague and smallpox can be considered as banished. On the other hand, the campaign against endemic contagious diseases is constantly confronted by new tasks, since the greater social contact and the assemblage of large groups, especially of children, have been accompanied by an increase in these infections. Thus diphtheria has been on the upgrade, although the disease has generally run a mild course. A reported total of 3,000 new cases of tuberculosis represents only an apparent increase, which is based on better detection of the disease by the anti-tuberculosis centers of the health bureaus. These centers cared for 1.5 million citizens during 1936. The tuberculosis mortality in 1937 in cities of 15,000 and more inhabitants reached a new low of 6.9 per 10,000 of population. The number of tuberculous children as reckoned on the basis of excuses from attendance at school has declined from the former proportion of between one half and two thirds to only one third. Sharp recessions have been noted in the morbidity and mortality of typhoid, paratyphoid and dysentery.

The health bureaus have likewise been engaged in energetic campaigns for nursing and infant welfare. In the year 1935, which marked the establishment of the new type of health bureau, 857,000 nurslings came under their care. Of a total of 1,276,000 babies born in Germany in 1937, no less than 1,129,000 received the services of the bureaus. The nursing mortality in the same year dropped to 6.4 per cent.

Dr. Gütt said that the problem of drug and food poisoning has not yet received adequate attention. In 1936, 6.4 milliards of reichmarks were spent for alcohol and tobacco. The damage which results hygienically, economically and socially from the misuse of these substances is generally underestimated.

As a consequence of the national genetic policy, the number of marriages in the larger cities increased from 609,000 in the year 1936 to 620,000 (9.2:1,000) in 1937. The present natality, according to an estimate of the national bureau of statistics, amounts to around 18.7:1,000 (as against 14.7:1,000 in 1933). The mortality seems to remain substantially unchanged. According to the expectation of life of particular age groups, the mortality of the entire German reich in 1936 should have reached 17.8:1,000 of population, whereas actually, thanks to improved hygienic conditions, the rate amounted to only 11.8. The danger of an aging of the German nation can carry with it the threat of a higher mortality. The existence of all European peoples is threatened to a greater or lesser degree, and now as before Germany is no exception. But the danger of race suicide is considerably greater in countries other than Germany.

Dr. Gütt concludes as follows: The greater the number of individual citizens of a nation who lead pleasant, irresponsible lives without regard to their own intrinsic value and biologic function and at the expense of the genetically sound and pro-

lific families, the sooner will the nation in question disappear from the family of nations. The democratic political philosophy, until recently accepted in Germany, favors just such a decline. Among the contributing factors to a dying-out of the most gifted and valuable members of society are celibacy, bachelorhood, homosexuality and advanced age at marriage of precisely the best-educated and most socially fit classes of society. If this trend were allowed to continue unchecked the white peoples and especially those of Germanic stock would become unfit to compete with other races in the biologic struggle for survival. Therefore, eugenics should be the cornerstone of a national political philosophy.

Prof. Paul Strassmann Is Dead

The illustrious Berlin gynecologist Prof. Paul Strassmann died recently at Gstaad, Switzerland, at the age of 72, after a brief illness. With him passes a most valuable contributor to the science and practice of his specialty. Strassmann came of an old Berlin family which had produced a whole series of distinguished physicians. He enjoyed an excellent training as assistant to Löhlein at Giessen, spent two years of study in England and returned to work for eight years with Gusserov in Berlin (at the Charité clinic). Later he established his own clinic, which came to be highly regarded. Strassmann's scientific contributions to obstetrics were numerous and valuable. In 1911 he received the degree of doctor honoris causa from the University of Birmingham. He was an honorary member of the St. Louis Gynecologic Society and corresponding member of the gynecologic society in Rome. His likable personality was everywhere esteemed.

Exanthematous Typhus in Bessarabia

M. Smadu, chief superintendent of health affairs in Bessarabia, has made a study of the causes, treatment and prevention of exanthematous typhus. This disease can be traced back to 1904, when it became epidemic. In 1919, 50,400 cases were recorded; in 1920, 31,246; in 1921, 3,486; in 1922, 2,196; in 1923, 3,347; in 1924, 2,217; in 1930, 1,140; in 1931, 951; in 1932, 1,313; in 1933, 1,225; in 1935, 2,400; in 1936, 4,227, and in 1937, 3,690. Thus typhus spent its fury after the war, then assumed a milder form and in the last three years appeared in a more vehement form as a consequence of bad economic conditions. The population, so to speak, marched out from the villages looking for food in distant regions. Such an exodus involved negligence of hygiene. The decrease in the number of cases in 1937 is attributable to the activities of the thirty-eight health detachments. The regular public health personnel is unable to spare time for the destruction of vermin in the houses. The area covered by the district physicians is in some cases huge and the roads in Bessarabia are almost impassable; thus the infection spreads rapidly. The detachments set up many disinfecting ovens and baths and taught the population how to live hygienically. The result was a decrease in the number of cases in 1937. Besides these detachments, seventy-seven young physicians were placed in service in the campaign. Three years ago a law was passed by the chamber of deputies according to which the compulsory military service of medical students lasts a year, half of which must be spent in the country.

The detachments were supplied with cauldrons for washing clothing and with irons, razors and hair-cutters. As there was a great shortage of underwear the ministry of health distributed 17,000 shirts among the poor. This gesture reduced the aversion of the population toward the detachments. The deparasiting detachments disinfected 182,774 houses and deloused 751,710 inhabitants.

The public health personnel of Bessarabia prior to the war consisted of 112 district physicians, 203 subordinate officials and eighty graduated midwives. Immediately after Bessarabia joined Rumania, the public health ministry increased the number of physicians to 207, that of the subordinate officials to 302 and that of the midwives to 136. Three years ago independent health inspectorates were established in seven counties of Bessarabia. It is necessary, says M. Smadu, that in every village at least one subordinate health official be engaged. In many communities there are a great number of families who do not know what soap is, and lack of personal cleanliness is a potent factor in the spread of exanthematous typhus.

According to M. Smadu, the campaign against exanthematous fever can be successful only if the whole population of Bessarabia is simultaneously subjected to deparasitation. He ordered the conscription of all clergymen, teachers, officials, public health subordinates and midwives, and in the nine districts found 9,300 such persons who will work in the service of deparasitation twice annually for six days without compensation. Their tasks are to supervise the population of the village, exert an influence from a hygienic point of view and deparasite the homes. M. Smadu proposed to the minister of culture that he instruct the 4,300 teachers of Bessarabia's children to instruct the rural population in personal cleanliness. In one village of the county of Cetatea Alba, with a population of about 5,800, more than 3,000 inhabitants were suffering from scabies, and the fourteen teachers of the village left the whole deparasiting work on the shoulders of the subordinate health official.

M. Smadu introduced two annual cleaning weeks, one before the Easter holidays and the other in October. Observance of these weeks is enforced by the clergymen, teachers, notaries public, subordinate officials and midwives. Great attention is given also to personal deparasitation. Doubtless at the beginning of this campaign the deparasiting was not perfectly done, but from 50 to 70 per cent of the population yielded to the requirements. Conscientious work carried out for a few years not only will exterminate exanthematous typhus but at the same time will accustom the rural population to cleanliness and hygienic living.

SWITZERLAND

(From Our Regular Correspondent)

Sept. 1, 1938.

The International Congress of Physiologists at Zurich

The sixteenth International Congress of Physiologists was held at Zurich August 14-19. Prof. W. R. Hess, Zurich physiologist, presided. It was especially appropriate that this meeting should take place in Switzerland, for this year the fiftieth jubilee of such congresses was celebrated and their origin under Swiss auspices was recalled. It was in 1888 that Friedrich Miescher, the renowned professor of physiology at Basel, invited physiologists of all lands to a first international assembly in Basel University's Institute of Physiology, only just opened at the time. The idea of arranging an international meeting of physiologists in Switzerland was suggested to Miescher by the British Physiological Society. The first congress was held Sept. 10-12, 1889, at Basel. Since that time the attendance at the congresses has increased nearly tenfold. At the 1889 congress many contributions of scientific importance were made. To mention a few of the more noteworthy: Von Mering and Minkowski submitted their classic studies of the pancreas; Mosso exhibited his ergograph, Goltz his decerebrized dog and Waller the first electrocardiogram, and Horsley demonstrated the motor functions of the cerebral cortex in apes. An account of the international congresses, which one might say is at the same time a history of the advances in physiology, is contained in a handsome commemorative volume, which the Physiological Society of England dedicated to the Swiss National Committee

apropos of the Zurich congress and a copy of which was presented to each participant. (Franklin, K. J.: *A Short History of the International Congresses of Physiologists*, *Ann. Sc.* 3:15 [July] 1938). Another recent commemorative work was the animatedly written, beautiful homage volume dedicated by the Swiss physiologists to Albrecht von Haller, the great Swiss physiologist of the eighteenth century. The author of this work was Johannes Strohl.

The first congress at Basel, in 1889, was attended by 129 scientists; more than 1,200 attended this year's meeting. At the 1889 congress twenty-five papers were read and twenty-three demonstrations performed; in Zurich this year the discussions and demonstrations numbered about 600. These statistics give some idea of the concentration necessary to assure smooth functioning of the transactions of the 1938 congress, as well as of the huge tangle of organizational problems which it befell the president, Professor Hess, and the secretary general, Prof. Ernst Rothlin (Basel) to unravel. Every country in the world in which the serious study of physiology is pursued was represented at the Zurich congress. The Americans present submitted an impressive series of papers. The congress performed a particularly valuable service in that through a large number of so-called arrangements of discussion important problems that claim the attention of the scientific world were introduced by authoritative workers in the field and thus opened to general discussion. It was in these discussions that the 1938 congress attained a level superior to that of any previous congress.

TOPICS

The following list of the more important topics and the men who introduced them offers a general idea of the ground covered by the congress: Functions of the different parts of the renal excretory system, A. N. Richards of Philadelphia and Brandt Rehberg of Copenhagen; interrelation of local metabolism and circulatory regulation, Rein of Göttingen and Fleisch of Lausanne; cholinergy and adrenergic, Bacq of Liège and G. L. Brown of London; hydration of the animal organism and the physiologic reversibility of oxidative abba reactions, Knoop of Tübingen and Szent-Györgyi of Szeged, Hungary; permeability of the skin to medicaments and poisons, Flury of Würzburg and Bürgi of Berne; cellular parameter and the regulation of stimulus, K. S. Cole of Columbia University, New York, and Lullies of Cologne; effective substances of the sterol series, E. Laqueur of Amsterdam; respiratory problems of fetal life, Barcroft of Cambridge and Roos of Utrecht; problems of national nutrition, Abderhalden of Halle and Quagliariello of Naples; reflex regulation of respiration, Heymans of Ghent, Belgium, and R. A. Gesell of Ann Arbor, Mich.; the adrenal cortex, E. C. Kendall of the Mayo Foundation, Rochester, Minn., and Verzar of Basel; the hormone of the anterior lobe of the hypophysis, Houssay of Buenos Aires and K. J. Anselmino of Elberfeld; yellow respiratory ferment (vitamin B₂), Theorell of Stockholm and H. Chick of London; potential toxic effects, Tiffeneau of Paris and Gremels of Marburg.

The general discussion of a particular theme was in each instance begun by a notable contributor. The administration attempted in every possible way to effect a helpful collaboration between scientists from far-flung lands. The scientists were made conversant beforehand with the full program of the congress. To the printed program (of some 130 pages) was appended a series of abstracts of the individual reports prepared by the authors, and in addition each participant received two volumes entitled "Congress Reports I and II," which contained two indexes, one (71 pages) to the reports which were to introduce various topics of discussion and the other (394 pages) to the demonstrations and individual lectures. These preliminary measures placed the transactions on a sound basis and contributed to the scientific success of the

congress. Supplementary printed matter was run off from day to day. Unfortunately, the large number of master topics necessitated the holding of frequent parallel sessions. Four or more reports were sometimes read simultaneously to different sections. The spacious new home of the Confederate Institute of Technology was placed at the disposal of the congress, and the simultaneous discussions could there be held in adjacent rooms. As the demonstrations took place in part in this building and in part in nearby quarters, one could get about easily from one exhibit to another. Many of the demonstrations, including the motion picture exhibits, were repeated several times. Consequently in the course of those crowded days, every physician had an opportunity to attend the demonstrations that most interested him.

SESSION FOR PHARMACOLOGISTS

As everybody knows, the pharmacologists have to date never held an international congress of their own, although efforts to bring about such a meeting have been under way for some time. Accordingly pharmacologists in large numbers appeared at the congress of the sister science physiology. Many themes of discussion pertained to the province of pharmacology. At one entire afternoon session, completely given over to the pharmacologists, the chief topic was "The Scope and Future of Pharmacology." Introductory papers were read by Sir Henry Dale, London, and Prof. Walter Straub, Munich. At the end of this session the question of an international nomenclature was discussed and the present inconvenience of a plurality of names for single pharmaceutical substances deplored. Prof. Wolfgang Heubner, Berlin, was the principal speaker on this topic. The discussion was concerned with strictly scientific terms and not at all with the nomenclature of proprietary products. One gained the impression that the question of nomenclature will in future receive greater consideration.

RESULTS

On the whole, the 1938 congress provided a highly instructive cross section of our knowledge of the field of physiology. Its scientific mission may be said to have been fulfilled, but it served another purpose as well: greater personal collaboration among scientists. Such a collaboration has a twofold value. There is the human interest value incident to personal acquaintance with colleagues in one's own specialty, and there is the more practical consideration that problems may be elucidated and misunderstandings composed much more readily through personal contact and discussion than through the less direct avenues of correspondence and publication. For the promotion of a feeling of personal collaboration, such an important function of these congresses, the Swiss committee had planned the most elaborate facilities; these were taken advantage of by large numbers of the visitors and well served their purpose. The general feeling at the conclusion of the convention was appreciation for the work of the Swiss officials in this regard. At the final session complete satisfaction with the organization arrangements was expressed. On the invitation of the Physiological Society of England it was decided to hold the next congress in that country three years hence, at London, Oxford or Cambridge. The congress voted the establishment of a permanent international secretariat of physiologists to be located in Switzerland. This bureau, for which the Association of Swiss Physiologists has assumed responsibility, is designed to facilitate the administrative details of future congresses and to maintain closer relations between the various national societies of physiologists.

CONGRESS ON ALTITUDE PHYSIOLOGY

After the Zurich congress, the physiologists particularly interested in the problems of the physiologic reaction to high altitudes held a "Congress on Altitude Physiology." This meeting was held on the ridge of the Jungfrau; ninety scientists took part.

Prof. Alexander von Muralt, Berne physiologist, presided. Discussion was elicited by reports on various topics: the effects of altitude on the respiration, the circulation and the blood; mountain climate, the formation of snow and ice, a research expedition into the Chilean Andes and the physiologic station on Mount Etna. In addition there were demonstrations at the Jungfrau-Ridge High Alpine Research Station and motion pictures.

PALESTINE

(From a Special Correspondent)

TEL-AVIV, Aug. 23, 1938.

Medical Progress in Palestine

Before the outbreak of the World War, modern standards of medical practice and hygiene were practically unknown in Palestine. To the Arab but one disease was known, "harrara," a term for all communicable diseases, including malaria, and all infections of the eyes. Since in most cases conditions diagnosed as conjunctivitis were in reality trachoma, "harrara" might also indicate the presence of this infection. Similarly, all serious infections of the skin were called "harrara." At the time of the British occupation, there were only a handful of physicians in the country, and but few of them had enjoyed the advantages of medical training in Europe. Hospitals were in an equally backward state. They had been founded by missionary societies and were utterly lacking in modern facilities. The superintendent not only was engaged in administration but was at the same time internist, surgeon and gynecologist. With the cessation of hostilities, Jewry turned to Palestine and a steady stream of young progressive elements began to pour into the country. They came first in small groups from Central and Eastern Europe and later in larger numbers from both Eastern and Western Europe, bringing with them standards of medical aid, which they wished to embody at once in their "new homeland."

MEDICAL WORK OF HADASSAH

The Women's Zionist Organization of America, Hadassah, which today numbers 60,000 members, made possible the organization of medical aid on a modern basis. The medical activities of this organization, begun in 1913, were abruptly curtailed by the outbreak of the war. In response to an appeal from the World Zionist Center in London, Hadassah undertook to send a medical expedition to Palestine. The first American Zionist medical unit, composed of doctors, nurses, bacteriologists and sanitary engineers, arrived in 1918, while war was still being waged in the country. This unit began at once to combat epidemic diseases, especially malaria. A chain of dispensaries was opened in towns and colonies. Hospitals were established in Jerusalem, Tel-Aviv, Haifa and Safad. Infant welfare stations were set up in every part of the country and their services extended free of charge to all, regardless of race or creed. School hygiene was introduced, with special emphasis on dermatologic and ophthalmic treatments. The spread of communicable diseases was combated with success, and improved standards of hygiene were introduced into the home. When Hadassah began its work the incidence of trachoma was high. Owing to intensive treatment the rate in the Jerusalem schools was reduced from 21.6 per cent in 1918 to 3.27 per cent in 1935. The efforts of the first Hadassah sanitary squad have been vastly enlarged. Extensive antimalaria drainage has been carried out in cooperation with the Jewish National Fund and the Palestine Jewish Colonization Association ("Pica"), and malaria-ridden districts have been reclaimed for colonization.

It was apparent that an inexperienced community absorbed in intense upbuilding could not yet maintain an effective medical system without outside aid. From the outset it was a part of Hadassah policy to initiate new enterprises and continue their maintenance only until the work was justified in the eyes of the public and the community was able to assume financial responsibility. With the growth of the Jewish community and the

improvement in its economic conditions, Hadassah began a program of transferring its institutions to local bodies. The work was begun with the transfer of its hospitals outside Jerusalem. Transfer of health, welfare and rural medical services followed. These services were concentrated in a newly organized rural insurance institution, known as the Kupat-Holim-Amamit, which extends its benefits to farmers and other elements not affiliated with the General Federation of Jewish Labor. This assumption of responsibility by local communities is enabling Hadassah to fulfil its original purpose, the founding in Palestine of that which is beyond the resources of a relatively small and pioneer community. Under these circumstances, Hadassah, in cooperation with the American Jewish Physicians' Committee under the leadership of Dr. Ratnofsky, has undertaken to establish a medical center on Mount Scopus.

COOPERATIVE SCHEMES FOR MEDICAL AID

Jewish pioneers who had come to Palestine to remold their lives could not become passive recipients of medical aid. Even before the arrival of the Hadassah medical unit they had initiated cooperative schemes for medical aid. These independent efforts were continued until they succeeded in developing an important health insurance organization, Kupat-Holim of the General Federation of Jewish Labor in Palestine. From a membership of 2,000 in 1929 the organization has made rapid strides and today numbers 75,000. Including members' dependents, it provides medical service for about 140,000 persons, or about one third of the total Jewish population of Palestine. In a country in which no compulsory health insurance legislation has been enacted this is truly remarkable. While agricultural workers were the founders of the organization, today its ranks embrace skilled and unskilled workers in town and village, workers in every branch of industry and public works, clerical workers and members of the liberal professions. The benefits of the service have augmented its membership from year to year and have gained the cooperation of an increasing number of employers who pay their contributions of their own volition. In various undertakings employing both Jews and Arabs this contribution is paid, and all workers, including hundreds of Arab laborers, enjoy its institutions. The rural dispensaries of Kupat-Holim and Hadassah have always extended aid to the Arabs of the district. It was at one time not uncommon for whole families to trail tens of miles for treatment during the summer, when epidemic diseases are prevalent. These rural medical centers not only treated the sick and ailing but endeavored to teach the principles of hygiene to wandering Bedouins and peasants, hitherto healed by the charms of the medicine man.

The workers' health insurance organization, Kupat-Holim, conducts 165 dispensaries; three central dispensaries in the principal cities; two hospitals, one in the Valley of Jezreel and one in the Sharon, near Petach-Tikva, and two convalescent homes, one on Mount Carmel and one in the Judean hills near Jerusalem. Pharmacies are attached to its rural and urban dispensaries; modern x-ray machines are installed in its central dispensaries and hospitals; physical therapy clinics and a central analytic laboratory provide its members with special services. It employs 300 physicians, most of whom have come from Europe, 200 nurses, forty dentists, thirty-five pharmacists and a large staff of clerical and technical assistants. The Jewish health enterprises herein described were initiated and developed independently by various organizations. In time it became apparent that the coordination of their activities demanded a central body. This need found expression in the establishment of a health council, consisting of seven members and four ex officio members; the directors of the Hadassah medical services, of the workers' health insurance organization and of the rural insurance society, and a representative of the municipality of Tel-Aviv. This council fulfils various functions for the community as a whole.

Hospital Service

Most of the hospital care in Palestine is provided by voluntary agencies and municipal bodies.

The workers' health insurance organization accompanied the pioneer to outlying, malarial areas, where he was breaking ground for new settlements. At the first cooperative settlement established in the Valley of Jezreel, at Ain Harod, the first hospital unit was opened in 1923, in huts under primitive conditions. The first permanent buildings of the hospital were erected in 1929, and various units have since been added. The hospital lies in the heart of an agricultural area and was intended for the labor settlements of Lower and Upper Galilee. As it was for years the only hospital with a well equipped medical section, patients were sent from Haifa as well as from Galilee. Similarly, its gynecologic, maternity and pediatric wards were forced to admit patients from the Haifa district. The enlargement of its x-ray department and the acquisition of an electrocardiograph during the past year have provided modern diagnostic facilities for the hospital as well as for the dispensaries of the vicinity. The hospital has sixty beds and its records show a 100 per cent occupancy in 1937. During this period 2,018 patients were admitted, representing 25,911 sick days, or an average of 12.8 days per patient. The hospital is faced with two main difficulties. Since it lies in a new colonization area, the scope of its jurisdiction is being constantly enlarged and not infrequently by the addition of malaria-infected areas. It is greatly handicapped by the lack of a proper surgical department. Emergency cases are treated, but all transportable patients are referred to the nearest surgical department at Haifa. This is at no time advisable and is fraught with danger in view of the present unrest in the country. Political upheavals in recent years have restricted the opportunities for graduate study abroad. Such study has been in part replaced by an intensive program of clinics and conferences in which local specialists as well as visiting physicians from abroad have participated. The Afuleh branch of the Julius Jarcho Medical Library of the Hebrew University has been transferred to the hospital and provides the physicians of both the hospital and the district with modern medical books and periodicals.

The second hospital of the workers' health insurance organization, the Belinson Hospital, opened in October 1936, is situated on the Petach-Tikva Road about ten miles from Tel-Aviv in the heart of a citrus fruit area. The following units have been completed: (1) a 100 bed hospital containing four wards (medical, surgical, gynecologic-obstetric and pediatric), operating and supply rooms, an x-ray division, a laboratory and a small pathology building; (2) housekeeping and service rooms, and (3) quarters for the physicians, general staff and persons in training. The construction of the present buildings entailed an expenditure of £P. 50,000, of which £P. 8,000 was contributed by the Palestine government and the balance raised by Kupat-Holim. An unusual shortage of beds and the suffering thereby entailed for its members forced the workers' organization (which is not a publicly supported institution) to undertake the construction and maintenance of this institution. The demand for hospitalization has been beyond its capacity. The average daily occupancy for 1937 was ninety-eight (including that of the nursery, 120). The first half of 1938 showed an increase of 10 per cent. In consequence of this demand for beds only seriously ill patients are admitted.

Facilities for proper ventilation were provided in all the wards, and an air-conditioning plant was installed in the nursery; such facilities are of inestimable importance in our subtropical climate. The hospital has been fully equipped with modern facilities for diagnosis and therapy. The following apparatus was acquired during 1937: electrocardiograph, thoracoscope with thorac-acoustic attachment, gastroscope, Macknesson gas apparatus for administration of nitrogen monoxide-ether and a surgical diathermy machine. Operations on the nose, throat, ear and oral

cavity are performed by specialists. A few months ago a chest surgeon of long experience was attached to the staff, and special attention is being given to his division. Except the specialists mentioned, all physicians, including departmental heads, are on full time and in residence. An enlightened attitude on the part of the members makes possible autopsies and microscopic examinations of tissues for pathology. Pathologic specimens are being saved, and it is hoped in the course of time to build up a valuable collection. The nucleus of a medical library is found in the hospital. Thanks to the assistance of Dr. Jarcho of New York City, new books and some forty current periodicals are received regularly. Interesting cases are presented in weekly clinics, to which the physicians of the district dispensaries are invited. The Kupat-Holim School of Nursing is attached to the hospital. It was opened over two years ago and now has an enrolment of fifty-one.

THE MEDICAL CENTER OF THE HADASSAH UNIVERSITY HOSPITAL

The new medical center of the Hebrew University will consist of three units: the Rothschild-Hadassah University Hospital, the Henrietta Szold Hadassah School of Nursing and the Nathan Ratnoff Medical School.

The hospital will provide from 270 to 300 beds, and additional structures in the future will permit an optimum capacity of 500. European and American experience in hospital construction have been adapted to the needs of the country, and a building which stands out for the simplicity of its lines has been achieved. Modern improvements and developments have been fully provided for in the equipment. No ward is to contain more than five beds. Most rooms will contain but three beds, and a limited number of single and double rooms will be available. Kitchen, laundry and other facilities have been equipped with the latest apparatus. Laboratories and lecture halls provide special facilities for clinics, research and instruction. The hospital will contain the following departments: general, surgery, gynecology, ophthalmology, dermatology, neurology, cancer and a special maternity pavilion to be named in memory of Paulina Ratnoff. The buildings are to be surrounded by a garden overlooking the Hills of Moab and the Dead Sea to the east and to the west the old city of Jerusalem and the ancient seat of the temple.

The school of nursing will be housed in a three story building. Lecture halls and laboratories will be located on the ground floor. The second and third stories will contain dormitories for persons in training and for a small number of nurses. The school will continue to prepare fully qualified nurses for Hadassah and other medical institutions.

The three story medical school building will contain laboratories for clinical research, lecture rooms for hygiene, bacteriology, serology, parasitology, pathologic chemistry, pathology and cancer and hormone research laboratories. An additional story to be constructed will contain laboratories for physiology and pharmacology and other branches as required. The cost of the three units, including equipment, will amount to £P. 170,000. This amount has been raised by the American Committee for the Erection of Hospitals in Palestine, comprising representatives of Hadassah and the American Jewish Physicians' Committee. Hadassah will continue to manage the hospital and the school of nursing, while the university will organize the teaching and research work. A special preparatory committee, consisting of representatives of the university, of the Jewish National Council and of Hadassah, will deal with teaching and research problems so far as they concern both institutions.

Medical Activities of the Hebrew University

In 1925, when the Hebrew University was officially opened, plans were made for the establishment of a medical division. The American Jewish Physicians' Committee, under the chairmanship of Dr. Ratnoff, made possible the erection of a microbiology building and the establishment of a parasitology

department. In 1926 the medical committee of the joint distribution committee contributed the means for the department of hygiene and bacteriology. Dr. Kligler of Columbia University and the Rockefeller Institute, New York City, was summoned from Haifa, where he was at the time directing the government station for malaria research, to head the department. The departments are making progress and now have a staff of ten collaborators of scientific standing, as well as younger assistants and a technical personnel. The department of bacteriology and hygiene devotes itself primarily to serologic and epidemiologic questions as related to the epidemiology of malaria, and a special station for this purpose was established at Rosh Pinah. The department of parasitology, under Prof. Saul Adler, deals with medical entomology and helminthology. In the medical graduate school, the following professors have been appointed in the clinical departments: Dr. B. Zondek, gynecology, and Dr. Halberstaedter, radiology.

An anonymous gift received by the University in 1935 for cancer research made possible the establishment of two new departments, those of radiology and experimental pathology. Both laboratories are fully equipped with modern apparatus and are being housed in the Nathan Strauss Health Center until the completion of the medical center on Mount Scopus. A special roentgen ray apparatus has been set up which permits rays of varying wave lengths to be produced in exceptionally powerful doses. Special attention has been paid to the investigation of tumor-producing powers of rays and, on the other hand, to the possibilities of producing therapeutic effects on tumors by means of rays. The department of experimental pathology considers its chief task to be the study of physiologic processes leading to cell division. This study is based on "tissue culture." In addition, the department is investigating purely pathologic problems. Particular mention should be made of the study of leukemia, with special reference to the possibility of growing the virus of leukemia, and its relation to cancer-producing agencies.

In the past six years the university has taken measurements of the intensity of the sun's radiation in the mountain districts surrounding Jerusalem and occasionally on the shores of the Dead Sea and the Mediterranean. These experiments, which are unique in the Near East, have already revealed that the solar energy which reaches the earth is greatest on fine winter days and least on the hottest days of the year. Ultraviolet sun rays are being investigated at five different points. Part of the necessary means were put at the university's disposal by the Kupat-Holim.

Marriages

JOHN D. WORKMAN, Lake Worth, Fla., to Miss Edith Beatrice Burrell of Biltmore, N. C., at Jacksonville, Fla., August 22.

JOHN PIERCE LAMBERT, Scarsdale, N. Y., to Miss Catherine Grant Nelson of Rocky Mount, N. C., at Clayton, Ga., August 15.

ROBERT NELSON SMITH, Comanche, Texas, to Miss Elizabeth Ada Lambert of Montclair, N. J., September 24.

GRADY CORNELL SISKE, Pleasant Garden, N. C., to Miss Robbie Emily Dunn of Greensboro, August 22.

JOSEPH R. CATON, South Bend, Ind., to Miss Margaret McMeel of Great Falls, Mont., September 3.

JAMES V. SACCHETTI, Worcester, Mass., to Miss Kathryn R. Sacino of Fitchburg, June 22.

FRANK H. POWER to Miss Margaret Goodrich, both of Ann Arbor, Mich., July 30.

SAMUEL R. MERCER to Miss Helen Cooper, both of Fort Wayne, Ind., September 3.

MAXWELL D. FLANK to Miss Ada R. Schwartz, both of Brooklyn, August 28.

HERMAN WECHSLER to Miss Rosalind Stieglitz, both of New York, September 11.

Deaths

Alonzo Gale Howard ☉ Boston; Boston University School of Medicine, 1895; professor emeritus of orthopedic and fracture surgery at his alma mater; consulting orthopedic surgeon to the Massachusetts Memorial Hospitals; member of the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; aged 68; died, July 4.

Morris Jacob Lesoff ☉ Far Rockaway, N. Y.; University of Vermont College of Medicine, Burlington, 1911; member of the Radiological Society of North America; on the staff of St. Joseph Hospital, Far Rockaway, South Nassau Communities Hospital, Rockville Center and the Meadowbrook Hospital, Hempstead; aged 53; died, July 2, of heart disease.

Maurice Edward Barron, Boston; Tufts College Medical School, Boston, 1914; member of the Massachusetts Medical Society; professor of clinical surgery at his alma mater; fellow of the American College of Surgeons; on the staff of the Beth Israel Hospital; aged 46; died, August 22, in Bristol, R. I., of coronary occlusion.

Harry Sands Weaver Sr., Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1892; professor of laryngology, rhinology and otology at his alma mater; member of the Medical Society of the State of Pennsylvania; fellow of the American College of Surgeons; aged 70; died, July 7, of carcinoma of the bladder.

Nelson O. Brooks, Oneida, N. Y.; University of Buffalo School of Medicine, 1894; member of the Medical Society of the State of New York; member of the House of Delegates of the American Medical Association, 1917, 1918 and 1926; formerly city health officer and coroner; aged 70; died, July 5, of coronary thrombosis.

Joseph Wiener ☉ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; fellow of the American College of Surgeons; on the staffs of the Mount Sinai Hospital, St. Joseph's Hospital and the Rockaway Beach (N. Y.) Hospital; aged 66; died, August 28.

Joseph Aladin Barre, Fall River, Mass.; College of Physicians and Surgeons, Baltimore, 1892; member of the Massachusetts Medical Society; at one time a member of the police board and of the board of health; on the staffs of the Union Hospital and St. Anne's Hospital; aged 69; died, July, 25.

Charles R. Ziegler, Carrollton, Ohio; Jefferson Medical College of Philadelphia, 1874; member of the Ohio State Medical Association; past president of the Carroll County Medical Society; county physician; aged 88; died, July 30, as the result of a fall suffered several months previously.

Henry D. Smith, Washington, Kan.; Lincoln Medical College of Cotner University, Lincoln, Neb., 1897; member of the Kansas Medical Society; president of the Washington County Medical Society; veteran of the Spanish-American and World wars; formerly mayor; aged 63; died, July 19.

Joseph James Scroggs, Beaver, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; member of the Medical Society of the State of Pennsylvania and the American Academy of Ophthalmology and Otolaryngology; aged 61; died, July 19, of cerebral hemorrhage.

Thomas Ellsberry Gray, Winslow, Ark.; Kansas City (Mo.) Medical College, 1901; member of the Arkansas Medical Society; served during the World War; lieutenant colonel in the medical reserve corps; for several years mayor and member of the city council; aged 64; died, July 11.

William B. Clapper, Victor, N. Y.; College of Physicians and Surgeons, Baltimore, 1894; member of the Medical Society of the State of New York; on the staff of the Frederick Ferris Thompson Hospital, Canandaigua; aged 73; died suddenly, July 22, of cardiac decompensation.

John Arnold Urner, Minneapolis; University of Minnesota Medical School, Minneapolis, 1924; associate professor of obstetrics and gynecology at his alma mater and the graduate school; aged 42; died, July 16, in the Minneapolis General Hospital of cirrhosis of the liver.

John Edgar Bowman ☉ Greenwich, Conn.; University of Toronto Faculty of Medicine, 1889; member of the Medical Society of the State of New York; medical superintendent and owner of a sanatorium bearing his name; aged 79; died, July 21, of carcinoma of the prostate.

Samuel Ashby Grantham Sr., Joplin, Mo.; Marion-Sims College of Medicine, St. Louis, 1892; member of the Missouri

State Medical Association; veteran of the Spanish-American War; on the staffs of the Freeman and St. John's hospitals; aged 72; died, July 31.

Angier Bailey Hobbs, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; formerly medical director of the New York Life Insurance Company; aged 74; died, July 24, in Bronxville, N. Y., of heart disease.

Mayer Rosen, Philadelphia; Jefferson Medical College of Philadelphia, 1897; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 62; died, July 5, in the Jewish Hospital of ruptured dissecting aneurism.

Isidore Andrew McClellan, Buffalo; American Eclectic Medical College, Cincinnati, 1880; Civil War veteran; aged 87; died, July 24, in the United States Marine Hospital of injuries received in a fall, hypostatic pneumonia and chronic myocarditis.

Elmer G. Starr, Pasadena, Calif.; University of Buffalo School of Medicine, 1884; fellow of the American College of Surgeons; formerly emeritus professor of ophthalmology at his alma mater; aged 77; died, July 21, of coronary occlusion.

Jacob John Kocher, Palm Springs, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1906; Jefferson Medical College of Philadelphia, 1907; aged 61; died, July 15, in the Palo Alto (Calif.) Hospital of coronary thrombosis.

Guy Frank Robinson, Livermore, Calif.; St. Louis College of Physicians and Surgeons, 1905; served during the World War; aged 54; on the staff of the Veterans Administration Facility, where he died, July 15, of general peritonitis.

Thomas Robert Durkin Jr., Philadelphia; Georgetown University School of Medicine, Washington, D. C., 1936; resident to St. Vincent's Hospital; aged 27; died, July 5, in St. Agnes' Hospital of subacute bacterial endocarditis.

Kallman Meyer Davidson ☉ Boston; Albertus-Universität Medizinische Fakultät, Königsberg, Prussia, 1887; fellow of the American College of Physicians; on the staff of the Beth Israel Hospital; aged 76; died, July 22.

Benjamin J. High, Elmwood, Tenn. (licensed in Tennessee in 1891); formerly secretary of the Smith County Medical Society; aged 75; died, July 31, in the Central State Hospital, Nashville, of chronic myocarditis.

Thomas Joseph Cahill ☉ Cambridge, Mass.; Tufts College Medical School, Boston, 1907; served during the World War; on the staff of the Cambridge City Hospital; aged 54; died, July 4, of coronary occlusion.

B. Ethelbert Watterson, Continental, Ohio; Ohio Medical University, Columbus, 1902; member of the Ohio State Medical Association; for many years member of the board of education; aged 69; died, July 3.

James Hunter Wells, Portland, Ore.; University of Oregon Medical School, Portland, 1888; at one time a medical missionary; formerly city health officer; aged 72; died, July 3, in the Emanuel Hospital.

Robert Warren Ramsay ☉ Littlestown, Pa.; Jefferson Medical College of Philadelphia, 1886; an Affiliate Fellow of the American Medical Association; aged 79; died, July 18, of cerebral hemorrhage.

Albert Alonzo Tennant, Richmond, Va.; Leonard Medical School, Raleigh, N. C., 1904; aged 59; medical superintendent of the Richmond Community Hospital, where he died, July 12, of heat prostration.

Joseph Le Roy Stevens, Dayton, Ohio; University of Cincinnati College of Medicine, 1932; member of the Ohio State Medical Association; aged 39; was killed, July 31, in an automobile accident.

Marcus Benjamin Halpern, Newark, N. J.; Hospital College of Medicine, Louisville, Ky., 1906; aged 64; died, July 9, at St. Barnabas Hospital of cardiovascular renal disease and arteriosclerosis.

Charles Rea Dickson, Toronto, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1880; University of the City of New York Medical Department, 1881; aged 79; died, July 9.

John Lawson Norris, Hendersonville, N. C.; National University Medical Department, Washington, D. C., 1897; served during the World War; aged 64; died, July 28, of coronary thrombosis.

Harry S. Wolff, Memphis, Tenn.; Missouri Medical College, St. Louis, 1898; house physician to the B'Nai Brith Home; aged 67; died, July 26, of diabetes mellitus and angina pectoris.

William Davies Gibbon, Dunbar, Neb.; Sioux City (Iowa) College of Medicine, 1895; aged 64; died, July 5, in Rancho Santa Fe, Calif., of coronary sclerosis, duodenal ulcer and pyloric stenosis.

Milton L. Snyderman, Philadelphia; Temple University School of Medicine, Philadelphia, 1937; intern at the Mount Sinai Hospital; aged 25; died, July 11, of Hodgkin's disease.

Robert Toru Masuhara, Ann Arbor, Mich.; University of Michigan Medical School, Ann Arbor, 1935; aged 30; died, July 7, in the University Hospital of miliary tuberculosis.

Henry Tucker, Bellevue, Md.; Jefferson Medical College of Philadelphia, 1894; served during the World War; aged 67; died, July 19, of angina pectoris and arteriosclerosis.

Derk Mulder, Lynden, Wash.; Universiteit van Amsterdam Geneeskunde Faculteit, Netherlands, 1881; College of Physicians and Surgeons of Chicago, 1887; aged 76; died, July 3.

James Porterfield Hull Ⓢ Stockton, Calif.; University of California Medical Department, San Francisco, 1895; aged 66; died in July, of arteriosclerosis and coronary occlusion.

John Esler, Cereel, Alta., Canada; University of Toronto Faculty of Medicine, 1902; medical superintendent and owner of the Cereel Hospital; aged 60; died, in July.

Andrew J. Wood, Macon, Ga.; University of Georgia Medical Department, Augusta, 1881; aged 84; died, July 16, in the Macon Hospital of pulmonary tuberculosis.

Roy Oscar Miller, New York; University of Toronto Faculty of Medicine, 1911; aged 55; died, July 31, in Jersey City, when he fell from a third story window.

Monroe De Tar, West Palm Beach, Fla.; Medico-Chirurgical College of Kansas City (Mo.), 1901; aged 76; died, July 15, of acute dilatation of the heart.

Charles Belton Macartney, Thorold, Ont., Canada; Detroit College of Medicine, 1903; Queen's University Faculty of Medicine, Kingston, 1911; aged 62; died, July 27.

Jehu Franklin McCool, Boonville, Ind.; Indiana University School of Medicine, Indianapolis, 1909; served during the World War; aged 56; died, July 23, of pneumonia.

Feibisch Rukhaus Ⓢ Cleveland; Medizinische Fakultät der Universität Wien, Austria, 1924; aged 43; died, July 12, of an overdose of a narcotic, self administered.

John Thomas Martin, Battle Creek, Mich.; University of Louisville (Ky.) Medical Department, 1905; aged 57; died, July 30, of chronic intestinal obstruction.

Bishop Marvin Kendrick, Luverne, Ala.; Medical College of Alabama, Mobile, 1903; aged 60; died, in July, at a hospital in Montgomery of sclerosis of the liver.

Malcolm L. Jackson, Spicewood, Texas; University of Tennessee Medical Department, Nashville, 1894; aged 71; died, July 28, of carcinoma of the stomach.

Alfons Ludwig Hageboeck Ⓢ Davenport, Iowa; State University of Iowa College of Medicine, Iowa City, 1889; aged 71; died, July 28, of cerebral embolism.

Ono Polk Sala Ⓢ Davenport, Iowa; Milwaukee Medical College, 1897; formerly on the staff of the Mercy Hospital; aged 65; died, July 21, of angina pectoris.

James B. Bridges, Seattle; Rush Medical College, Chicago, 1882; member of the Missouri State Medical Association; aged 81; died, July 22, of arteriosclerosis.

Joseph Martin Swindt Ⓢ Chino, Calif.; Cornell University Medical College, New York, 1932; aged 32; was found dead, July 11, of poison, self administered.

Horace Ivey Thomson, St. Petersburg, Fla.; Chicago College of Medicine and Surgery, 1916; served during the World War; aged 45; died in July.

Carl Braun Groschner, Toledo, Ohio; Jefferson Medical College of Philadelphia, 1897; aged 64; was found dead, July 28, of a self-inflicted bullet wound.

Allen Harris Peek, Ventura, Calif.; Cooper Medical College, San Francisco, 1904; aged 60; died in July of illuminating gas poisoning, self administered.

John Tolson, Church Point, La.; University of the South Medical Department, Sevanee, Tenn., 1904; aged 55; died, July 18, of cerebral hemorrhage.

Loucase Norton Lenman, Washington, D. C.; Washington (D. C.) Homeopathic Medical College, 1896; aged 67; died, July 17, of coronary occlusion.

Joel E. Luther, Mountain View, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1897; aged 70; died, July 28, of heart disease.

Richard W. St. Benno, Glen Ellyn, Ill.; College of Medicine and Surgery Chicago 1910; aged 54; died, July 19, of valvular heart disease and nephritis.

William Fankuchen, Brooklyn; Long Island College Hospital, Brooklyn, 1902; aged 59; was found dead, July 27, of morphine, self administered.

Frederick Eiche, Lincoln, Neb.; Northwestern University Medical School, Chicago, 1903; aged 72; died, July 12, in the State Hospital of senility.

Fernando Aguilar, Albany, N. Y.; New York Medical College and Flower Hospital, New York, 1917; aged 57; died, July 26, of cholelithiasis.

W. George Meredith, Tewksbury Township, N. J.; Homeopathic Hospital College, Cleveland, 1886; aged 77; died, July 10, of chronic myocarditis.

Adam D. Blomeyer, Cape Girardeau, Mo.; Beaumont Hospital Medical College, St. Louis, 1891; aged 72; died, July 22, of cerebral hemorrhage.

Edwin A. Wilson Ⓢ Salem, W. Va.; Cincinnati College of Medicine and Surgery, 1898; aged 72; died, July 12, of coronary thrombosis.

Arthur Nelson Rowe Ⓢ Newport, Wash.; Rush Medical College, Chicago, 1913; aged 59; died, July 20, in Tucson, Ariz., of bronchial asthma.

John R. Moore, Coushatta, La.; Memphis (Tenn.) Hospital Medical College, 1895; aged 72; died, July 17, of thromboangiitis obliterans.

William Walter Latham Ⓢ Madisonville, Texas; Memphis (Tenn.) Hospital Medical College, 1896; aged 64; died, July 28, of angina pectoris.

John Corran McCauley Sr., Rochester, Pa.; Western Homeopathic College, Cleveland, 1890; aged 73; died, July 19, of arteriosclerosis.

Thomas George Loudon, Peterborough, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1919; aged 54; died, July 6.

James Henry Hinchcliffe, Philadelphia; Medico-Chirurgical College of Philadelphia, 1903; aged 63; died, July 28, of heart disease.

M. C. Smith, North Girard, Pa.; College of Physicians and Surgeons, Baltimore, 1887; aged 73; died, July 5, of diabetes mellitus.

James A. Ryan, Oklahoma City; Hospital College of Medicine, Louisville, Ky., 1887; aged 81; died, July 12, of carcinoma of the prostate.

Isaac W. Costen, Roanoke, Va.; College of Physicians and Surgeons, Baltimore, 1892; aged 70; died, July 1, of cerebral hemorrhage.

Oscar J. Jordan, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1890; aged 73; died, July 11, of heart disease.

Otto Paul Ludwig, Chicago; Milwaukee Medical College, 1909; aged 53; died July 25, of cerebral hemorrhage and hypertension.

James Carter Giles, Danville, Va.; University College of Medicine, Richmond, 1903; aged 62; died, July 29, of myocarditis.

James Eliakim Patrick, Bahama, N. C.; University College of Medicine, Richmond, 1900; aged 67; died, July 28, of myocarditis.

John Thomson Green, Hamilton, Ont., Canada; Western University Faculty of Medicine, London, 1912; aged 50; died, July 13.

R. T. Madison, Amorita, Okla.; College of Physicians and Surgeons, Keokuk, Iowa, 1876; aged 85; died, July 6, of senility.

Frederic Bacon Cullens, Ozark, Ala. (licensed in Alabama in 1897); aged 74; died, July 12, of heart disease and nephritis.

H. Earl Coger, Houston, Texas (licensed in Texas, under the Act of 1907); aged 64; died, July 30, of heart disease.

Harry Weldon Osgood, Bangor, Maine; Boston University School of Medicine, 1898; aged 67; hanged himself, July 5.

David O'Shea, Chicago; Rush Medical College, Chicago, 1883; aged 83; died, July 24, of carcinoma of the rectum.

L. A. Parks, Lancaster, Ohio; Starling Medical College, Columbus, 1882; aged 80; died, July 1, of pneumonia.

William H. Riley, Ridgway, Ill.; Eclectic Medical Institute, Cincinnati, 1880; aged 82; died, July 26, of malaria.

Ernest H. A. Allison, Denver; Denver College of Medicine 1893; aged 84; died, July 30.

J. G. Goodner, Georgetown, Tenn. (licensed in Tennessee in 1889); aged 79; died, July 10.

Bureau of Investigation

CHROMARAY—TRIORAY

The Therapeutic (?) and Commercial Possibilities of Color

Chrome-Therapy—or, to use plain English—"cure by colored lights," like most forms of modern quackery or faddism, plays on the public's little knowledge that proves so dangerous when applied to the treatment of human ailments. The nonmedically trained person has hazy—and usually erroneous—notions of the therapeutic value of ultraviolet and infra-red rays; he has equally vague ideas of the place that heliotherapy—sun treatment—plays in the treatment of disease; he has a dim recollection of what he learned about the spectrum when he attended classes in high-school physics. With these scraps of knowledge floating hazily within his cerebral horizon, what more plausible than the claims set forth in ponderous seriousness, whether by enthusiastic faddists or venal quacks, that human pathology is in some way due to "a disturbance of Color balance" or that it can be cured by restoring "Radio-Emanative Equilibrium by Attuned Color Waves"—whatever such verbal pyrotechnics may mean!

The commercial possibilities of the use of color as a "patent medicine" have been appreciated by various faddists and quacks for some time. The "Bio-Dynamo-Chromatic Diagnosis" of quack George Starr White; the "Chromo Therapy and Diagnosis" of America's most accomplished charlatan, Albert Abrams, immediately come to mind as two of the many cults that till this lush field. Then came Dinshah P. Ghadiali and his "Spectro-Chrome Therapy," Karl von Schilling's "Vita Chrome" and now the "Chromaray" and "Trioray" of E. A. Ernest of the Ernest Distributing Company of Milwaukee.

Mr. Ernest should be well qualified to expound the commercial possibilities of the spectrum. He might paraphrase by declaring, "Thar's gold in them thar colors!" A few years ago the Ernest Distributing Company described itself as the "Exclusive United States Distributors for Spectro-Chrome Equipment." It handled the fantastic gadgets put out by Dinshah P. Ghadiali, who has exploited Spectro-Chrome Therapy continuously for years—save for a period when he was serving a term in a federal penitentiary for violation of the Mann Act.¹

Ghadiali's thesis was that in health the preponderating color-waves of the elements in the human body—oxygen, hydrogen, nitrogen and carbon—are "in balance." When they get "out of balance" the human body is diseased; *ergo*, to cure disease, administer the colors that are lacking or reduce the colors that are too brilliant! According to Ghadiali, yellow light aids digestion, kills worms and builds nerves; violet depresses the heart; orange will cause vomiting; blue will build vim, vigor and vitality. And so on!

In the autumn of 1933 a Wisconsin newspaper, the Milwaukee *Journal*, conservatively described the Ghadiali gadgets, handled by Ernest, as "hocus-pocus." It was reported that Ghadiali threatened to sue the newspaper unless a retraction was made. While Ghadiali's bark is most ferocious and awe-inspiring, his bite is toothless. No retraction was made and Ghadiali brought no suit. Ernest, however, filed suit for libel against the paper, asking \$150,000 damages and \$35,000 special damages. This in spite of the fact that the *Journal* did not mention Ernest by name in its article. When the suit came to trial, the jury decided that the Milwaukee *Journal* was fully justified in characterizing Ghadiali's gadgets as quackery.

Later Mr. Ernest ceased acting as "exclusive distributor" of the Ghadiali devices, and by November 1937 he and Ghadiali had so far parted company that the latter brought an action in equity against Ernest, charging him with an infringement of a patent granted Ghadiali in 1925 for "certain new and useful improvements in color wave projection apparatus." It is a fact that on July 7, 1925, the Patent Office issued patent number

1,544,973 to Ghadiali for a gadget for projecting colored lights. This does not mean that the Patent Office was remotely concerned with the use to which the patentee would put his device. So far as the patent officials were concerned, it was a matter of indifference whether the patented article was used to spot-light a burlesque queen on the stage or to throw pretty colored lights on a shop-window display.

But before Ghadiali had brought his suit, Ernest was advertising—in 1936—that his company was acting as "National Distributor" for another "color ray" concern, that of Karl von Schilling, whose device was dubbed "Vita Chrome (Life Colors)." The von Schilling machine was said to be "Released by National Clinic for Color Ray Research" and to have been "Approved by the National Association of Color Ray Scientists." If there is, or ever was, such a "national clinic" or "national association," their colored lights must have been hidden under a bushel, for we have been unable to find any scientists, either in medicine or physics, who have ever heard of them. By December 1936 Mr. Ernest appears to have severed connections with von Schilling, and from then on seems to have put out his own colored-lights devices, the chief of which Ghadiali claims is an infringement on his own machine. If one is in the hocus-pocus business, why split the swag?

As previously stated, the Ernest devices are named, respectively, "Chromaray" and "Trioray." The former seems to be the one that copies Ghadiali's. It resembles essentially the "spot-light" used in theatres and dance halls to project colored lights on the stage or the dance-floor. The source of light is an electric bulb. The "Trioray" looks like three hand mirrors having metal frames with green and blue lenses, respectively, in the place of mirrors. These are used where electric current is not available, and merely focus the sun's rays through the blue or green lens on to the patient—or victim.

According to the Chromaray advertising, this device has been "Successfully Used for the Treatment of" a list of thirty pathological conditions ranging alphabetically from Accidents and Appendicitis through Cancer, Cataract, Diabetes, Heart Disorders, High Blood Pressure, Low Blood Pressure, Pneumonia, Rupture, Sinus Trouble and Sleeping Sickness to Tuberculosis and Venereal Disease. Lack of space doubtless was all that prevented a completion of the alphabetical list, for of course the Chromaray would be equally efficacious in the treatment of such conditions as Worms, Xerophthalmia, Yaws and Zymotic Zoophobia.

From the Chromaray advertising one learns that red light will "energize" the liver, yellow will move the bowels, orange will supply any need of calcium and green will kill germs and take the place of chlorine. In short, to quote from the ballyhoo booklet on Chromaray: "Color Therapy is 'chromochemical affinization,'" a statement that ranks with some of the jingles in "Alice in Wonderland" in clarity. The theory of Chromaray is that "Disease is a disturbance of Color balance, due either to the lack of Color in the body or the inability of the organs to absorb or assimilate the color element."

Among the "clinical reports" that appear in the Chromaray booklet is this gem:

"Mr. E. of Vineland, New Jersey, was cured of a terrible case of rheumatic ankylosis of the shoulder by thermolune baths [whatever they are!] and some massage in two or three weeks. Red glass was used over the part."

The incidental mention of "some massage" is quite in character. One might conceive such a report as:

"Little Jimmie X. was cured of a terrible case of diphtheria by the use of pink and blue lights and some antitoxin."

The Chromaray booklet also suggests that blue glass should be used when there are "very acute pains" in "cases of inflammable [sic!] rheumatism." The old idea of spontaneous combustion will not down.

Summing up its thesis, the Ernest Distributing Company delivers this *ipse dixit*:

"The earth has arrived at a Cosmic Cycle of Color Expression."

And thus once again does the unintelligible make its irresistible appeal to the unintelligent.

Correspondence

THE ROLE OF THE ADRENALS IN HYPERTENSION

To the Editor:—In THE JOURNAL, August 6, page 556, appeared a communication from W. B. Cannon concerning an article by Rogoff and Marcus entitled "The Supposed Role of the Adrenals in Hypertension," which was published in THE JOURNAL, June 25. Dr. Cannon has published articles with similar content and manifesting a similar personal attitude on previous occasions (e. g. *Endocrinologic* 6:24 [Jan.] 1930; *Pharos of A. O. A.*, May 1938).

Dr. Cannon has challenged our statements on which we base argument for serious deprecation of certain risky clinical procedures that can be justified by his so-called emergency theory. He objects to our criticism of the suggestion admittedly made by him (*Am. J. Physiol.* 27:64, 1911) "that hypertension might be dependent on adrenal secretion and that adrenal secretion might be continuously stimulated by circulating epinephrine." Furthermore, he is evidently concerned because we did not refer to certain of his articles. These would only constitute "emphasis on minor points—points having little meaning in relation to the main difference which is at issue" (cf. A. O. A. lecture), and I agree with the statement in his lecture that "value may follow from a polemic if the discussion is kept on a factual level."

Notwithstanding Dr. Cannon's suggestion that I am not cognizant of the literature concerning "chemical mediation of nerve impulses," I am sufficiently familiar with it to recognize much of what may be called clothing old ideas in new terms. Reliability of some of the methods of investigation may be questioned. Existence of chemical mediators that are recognized by acceleration of a denervated heart which has been found to be not completely denervated (Brouha, L. A.: *Science* 83: [Feb. 28] 6, 1936; Cannon, W. B.; Lewis, J. T., and Britton, S. W.: *Am. J. Physiol.* 77:326 [July] 1926) may be considered more or less hypothetical, especially since this nonspecific test object is equally good as a reagent for epinephrine and for accelerator substances from the thyroid, the liver and elsewhere! Nor does this subject have more than "little meaning in relation to the main difference which is at issue." Furthermore, his point that adrenal secretion does not play a role in the maintenance of normal blood pressure also has little meaning in relation to the main difference which is at issue. I would not suppose that Dr. Cannon could believe otherwise, for he contends that there is no adrenal secretion under conditions of normal quiet existence, when a normal blood pressure is nevertheless maintained. That epinephrine secretion from the adrenals is not essential for maintenance of normal blood pressure was demonstrated by Stewart and Rogoff (*J. Pharmacol. & Exper. Therap.* 10:1 [July] 1917; *Am. J. Physiol.* 48:397 [May] 1919) and by Rogoff and Dominguez (*J. Metabolic Research* 6:141, 1924; *Am. J. Physiol.* 83:84 [Dec.] 1927). The point under discussion is concerned with pathologic, not normal, blood pressure.

Rogoff and Marcus quoted from Dr. Cannon's published articles. The quotations represent fundamental premises on which the so-called emergency theory rests. These premises are a basis for the clinical practice of intervention at the adrenals as a means of treatment for diabetes and for hypertension, a practice which involves grave risk to human life and health. We published quantitative evidence that Dr. Cannon's statements, as quoted by us, are not tenable in the light of experimental investigation. Regarding the supposed "autogenous continuance of adrenal secretion," Dr. Cannon (*Am. J. Physiol.* 27:64 1911) stated "Thus also the persistence of the emotional state after the exciting object has disappeared can be explained." Only a few months ago (A. O. A. lecture) he stated "Actual records show that one minute of excitement may have bodily

effects lasting for fifteen-twenty minutes if the adrenals are present and only brief effects if the glands are absent. Actual records show that the production of adrenine in amounts which can have remote influence in the organism is unmistakable." If Dr. Cannon no longer maintains the conclusions which we have quoted from his articles, and if he will refer me to any published withdrawal, I will readily admit error. If these fundamental concepts, deduced from his experimental work, are now denied, on what support does the validity of the emergency theory rest?

In a personal communication to Dr. Cannon, Nov. 11, 1929, under similar circumstances, I stated "I sincerely regret that we have not been able to come to some closer agreement in the matter under discussion. My only interest in the disagreement that exists between us is a conscientious desire to reach a satisfactory scientific explanation of the role of the adrenals. To this end I have often hoped that in some way it might become possible for us to arrive at some premise in our work where we could, perhaps, find it possible to cooperate and strengthen each other's position in the interest of scientific progress." Such a premise may, indeed, now exist since Dr. Cannon apparently no longer believes in the validity of his statements which we quoted. J. M. ROGOFF, M.D., University of Chicago, Chicago.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MODE OF DEATH FROM PNEUMONIA

To the Editor:—What work has been done and what conclusions have been drawn as to the fundamental cause of death in lobar pneumonia? Is it respiratory or cardiac failure?

L. T. BROWNING, M.D., Kankakee, Ill.

ANSWER.—With the advance of knowledge some old questions, unless they are rephrased, lose their point. In death from lobar pneumonia, more fundamental problems are involved than whether respiration or cardiac action fails first. Death usually occurs in medical shock or in pulmonary edema. Both conditions are often associated with bacteremia. The mechanism of death from bacteremia is still not understood. Bacteria in the blood may produce their effect by changes in the nervous system or other tissues either by exhausting them, by depleting stores of essential body ingredients such as hormones or vitamins, or as the result of changes due to toxic substances from the bacteria, exotoxins or endotoxins.

Pulmonary edema may be due to an extensive lesion which obstructs the lesser circulation or to edema-producing substances coming from the infecting organisms. Medical shock may be due to dehydration resulting from either pulmonary edema or evaporation from the lungs and skin due to the fever. The mass against which the heart may contract is reduced because of the smaller blood volume, so that the heart may ultimately fail. Anoxia is aggravated by poor circulation; the heart is not pumping adequately for the reason just stated. When there is so-called cardiac failure, oxygen and infusions of dextrose and saline solution are more useful than digitalis or other heart stimulants. Direct stimulation of the respiration or the heart is not required.

MAXIMOW'S TISSUE STAIN

To the Editor:—What is the technic of the Maximow tissue stain?

M.D., Massachusetts.

ANSWER.—The stain referred to is probably the hematoxylin-eosin-azure II stain (Maximow). The tissues must be fixed in Zenker formaldehyde solution. Sections to be stained are mounted on slides, the paraffin or celloidin is removed from the sections before staining, then the slides are passed through compound solution of iodine diluted 1:3 with distilled water and 5 per cent thiosulfate solution washed in three changes of distilled water. (a) From the distilled water the slides are trans-

ferred to weak Delafield's hematoxylin overnight, 1 to 2 drops of the stock solution in 100 cc. of distilled water being used (the weak solution must be fresh every time). Only the chromatin and nuclear membranes should stain faintly. (b) The slides are placed in distilled water all day to remove excess stain from the connective tissue. (c) The counterstain is eosin-azure II solution with 5 cc. of eosin solution, 40 cc. of distilled water and 7 cc. of azure II solution. (This solution is made just before use, each part being added in the order given and can be used only once.) The stain is applied overnight. More or less eosin or azure II may be used according to the quality of stain desired. The stock solutions are eosin 0.1 Gm. in 100 cc. of distilled water and azure II 0.1 Gm. in 100 cc. of distilled water. (d) The slides are differentiated in 95 per cent alcohol, each slide being looked at frequently under the microscope, until the nuclei are deep blue and the collagenous fibers are pink. They are dehydrated quickly in two changes of absolute alcohol and cleared in two changes of xylene fifteen minutes each and mounted in Damar. Some blue is removed in the dehydrating alcohols, so the slides should be started through them before differentiation is complete. When differentiated properly the nuclei should be deep blue, the cytoplasm varying shades of blue, the smooth muscle pale lavender, the connective tissue fibers pale pink and the red blood cells orange red or pale green.

Delafield's hematoxylin should age four months before use and should not be used after it is eight months old.

TUBERCULOSIS IN MEAT PACKING INDUSTRY

To the Editor:—I would appreciate information as to the incidence of tuberculosis among persons working in meat packing plants where they frequently enter the refrigerator.

J. B. WILETS, M.D., Wilwaukee.

ANSWER.—A careful search has failed to reveal statistics concerning the incidence of tuberculosis among persons working in meat packing plants where they frequently enter the refrigerator.

The United States Department of Agriculture, Bureau of Animal Industry, Washington, D. C., has no available information on this subject.

Physicians connected with large meat packing plants in Chicago have stated that the incidence of tuberculosis among meat packing workers and those employed in and out of refrigerators is not higher than in the employees of the packing plants in general or higher than the incidence of tuberculosis in workers at large.

"DOUBLE HEARING"

To the Editor:—A woman of 68, definitely not a neurotic, complains that following an explosion in a telephone receiver in March 1932 she became deaf in the right ear for a day. Her hearing returned, but she experienced an effect of "double hearing." Every sound repeats itself like an echo. The echo effect is close to the original sound; for example, the word "father" sounds like "fatherther." Her blood pressure is 190 systolic, 100 diastolic, and a whispered voice is heard only at five feet on the right side. Other ear, nose and throat examinations, including caloric tests, are normal. The patient was examined by a competent neurologist, who does not find any other symptoms.

S. H. PORTNOY, M.D., Cincinnati.

ANSWER.—"Double hearing" may be of several varieties. One type is known as diplacusis dysharmonica. In this variety the patient complains of hearing the same sound but with a different pitch in each ear. The pitch in the affected ear is usually higher but may be lower than in the normal ear. Another type of so-called double hearing has been described by Kayser as diplacusis echoica. Sound heard in the affected ear is repeated more or less as an echo. These forms of "double hearing" may be due to disease in the middle ear or in the cochlea. There are a number of theories regarding the mechanism, but no really satisfactory answer is available.

A number of observers accept the Helmholtz resonator theory of hearing, which assumes that separate tones are analyzed not in the eighth nerve and its central pathways but in the cochlea, where individual or groups of hair cells are stimulated by only certain tones, depending on the location of these cells in the cochlea. In general, high tones affect the hair cells near the basal turn of the cochlea; low tones affect those near the apex. An injury to the basilar membrane or an exudate weighing it down will cause the latter to vibrate abnormally and hence cause the particular hair cells resting on this membrane to transmit a faulty message to the brain. Those subscribing to this theory feel that diplacusis binauralis dysharmonica and echoica are due to lesions in the cochlea and not in the middle ear. There are others, however, who feel that the pathologic condition may be in the middle ear.

This patient should have a complete examination of the hearing to determine why the whispered voice is only heard at five feet

on the affected side. Should the examination reveal a conduction form of deafness, treatment may be of considerable avail. From the few cases described in the literature it would appear that a fair number of these complaints seem to cure themselves spontaneously by the passage of time. It is quite possible that the acoustic insult described was responsible for the disturbances of which the patient complains.

EFFECT OF SULFUR CHLORIDES ON EYES

To the Editor:—What is the effect on the eyes, especially the macular bundle with a reaction similar to toxic amblyopia, from breathing fumes from sulfur monochloride or chloride? This is supposed to be oxidized on contact with air.

U. D. SEIDEL, M.D., Akron, Ohio.

ANSWER.—Sulfur chloride on contact with air is probably not oxidized but hydrolyzed to hydrochloric acid and possibly hydrogen sulfide or sulfur dioxide. There is no evidence that sulfur chloride or its hydrolytic products possess any special capacity to attack the macular bundle or to lead to toxic amblyopia, but sulfur dioxide and hydrogen sulfide irritate the mucous membranes including the conjunctiva. In fact, some writers indicate that sulfur chloride itself is nontoxic. Hamilton (Industrial Poisons in the United States, New York, Macmillan Company, 1929) states that sulfur monochloride "is apparently nontoxic" and quotes Lehmann as having noted that it is "practically harmless." However Kober and Hayhurst (Industrial Health, Philadelphia, P. Blakiston's Son and Company, 1924) state that the decomposition products of sulfur chloride are injurious. It is well known that hydrogen sulfide is a toxic chemical. In some industries, sulfur chloride is used in conjunction with carbon disulfide, in which case the latter substance is to be regarded as the more dangerous. Carbon disulfide has produced amblyopia, retinitis and bulbar neuritis but so far as known not as the exclusive manifestation of its action. More recently, sulfur chloride has been described as possessing damaging properties in its own right—jaundice, neuritis, myelitis and profound weight losses are said to be characteristic.

Adler, in the Proceedings of the Fifth International Medical Congress on Occupational Diseases, in 1928, reported clinical and laboratory work related to the action of sulfur chlorides. Earlier, Adler-Herzmark reported in International Labour Office studies (Industries Hygiene, 1926, No. 10, p. 76) poisoning by sulfur monochloride in the absence of carbon disulfide, in which the patient presented jaundice, great loss of weight, and paralysis of the forearms, legs, bladder and rectum. After a short period the major disturbances disappeared, leaving some atrophy of the leg muscles, associated with paralysis of these extremities. In general, it is believed that sulfur chloride or its hydrolytic products might induce injury to the eye, but apparently only in case there coexisted other and more characteristic evidences of injury from this source.

HYSTERECTOMY AND INCIDENCE OF CANCER

To the Editor:—Please let me have some information on (1) the incidence of thyroid disease after hysterectomy previous to the menopause; (2) the incidence of carcinoma of the cervix in patients following supra-cervical hysterectomy as compared with women not operated on; (3) the incidence of carcinoma of the cervix in hysterectomized patients before and after the menopause.

M.D., Ohio.

ANSWER.—1. As far as is known there are no statistics about the incidence of thyroid disease after hysterectomy previous to the menopause.

2. In a series of 7,244 subtotal hysterectomies collected from the literature by von Graff (*Am. J. Obst. & Gynec.* 28:18 [July] 1934) carcinoma was subsequently found in the cervical stump in forty-five instances, an incidence of 0.62 per cent. Likewise in the literature von Graff found that there were 176 cases of cancer of the cervical stump among 4,269 cases of cervical cancer, a frequency of 4.1 per cent of all cervical cancers. Von Graff says: "Comparing the 0.6 per cent post-cancers of cancer after subtotal hysterectomy with the actual frequency of 4 per cent of stump cancer, every unprejudiced observer must admit that the danger of cancerous degeneration, present at the time of operation or developed later, is more than six and a half times as great as ordinarily reckoned. In addition it is fair to presume that many instances exist which have not come to our knowledge. . . . The real frequency of stump cancers may amount to several times the number revealed in this paper."

It is essential to determine whether cancer in the stump of the cervix was present at the time of the supracervical hysterectomy or appeared later. Von Graff assumed that cancers found within one year after a hysterectomy were present at the time of the operation. In a series of 581 cancers of the cervical stump he found that 137, or 23.5 per cent, were present at the time of the supracervical hysterectomy and that only 76.5 per cent developed subsequently.

3. The age of patients with cancer of the cervical stump has no significance. This form of cancer occurs at any age from 20 to over 70 years. Whereas the large majority of the stump cancers occurred in women between 36 and 60 years of age, 11.3 per cent of von Graff's series were found in women between 20 and 35 years of age. Hence the possibility of this form of malignancy must be taken into account regardless of the youth of the patient. Approximately one third of the patients in von Graff's series were past 50 years of age.

HYPERTENSION AND ACUTE ANEMIA

To the Editor:—A man aged 56, once a nationally famous athlete, complained of frequent dizziness, slurring of speech, weakness in the legs (especially the left), nocturia and difficulty in controlling urination. Thirteen months ago physical examination revealed a slight deviation of the tongue to the right, a moderately hypertrophied heart, a blood pressure reading of 280/160, shuffling gait, and no appreciable objective loss of strength in the extremities. Rectal examination showed a slightly hypertrophied prostate. The blood vessels were slightly arteriosclerotic. Urinalysis showed granular casts, albumin 2 plus, specific gravity 1.011. The Wassermann reaction was negative. On a diagnosis of chronic nephritis with malignant hypertension, the patient was treated with phenobarbital, glyceryl trinitrate, theobromine with sodium acetate, digitalis, fluids freely, low salt diet and restricted activity. He improved considerably, the blood pressure descending to 160/120 at times, with frequent fluctuations to a maximum of 200 mm. systolic or over. Urinalysis was negative at frequent intervals and nocturia was less frequent. Three days ago the patient complained of an increase in the severity of his symptoms. The blood pressure was 280/160. He was hospitalized and on the next morning the blood pressure reading was estimated to be about 320/160, as it seemed to register about 20 mm. higher than the 300 mm. maximum possible on the sphygmomanometer. A venesection of 500 cc. of blood was done with a drop in pressure to 248/140. The patient felt better. He was placed on phenobarbital, glyceryl trinitrate and digitalis. About five hours after the venesection the patient suddenly became irrational, tried to get out of bed, had convulsive movements of the left extremities and then lapsed into a deep coma with frothing at the mouth. The blood pressure taken at this time was over 300 mm. systolic. He remained in coma until his death four hours later. My impression is that he died of apoplexy. Please discuss (1) the maximum heights of blood pressure ever recorded and prognosis at various levels, (2) changes of blood pressure from venesection and (3) diagnosis and treatment of such a case.

M.D., Hawaii.

ANSWER:—Probably the patient had had a minor cerebral accident when he was first seen, but the terminal episodes resemble acute uremia rather than cerebral apoplexy. The renal elements of his disease seem to have been neglected both diagnostically and therapeutically. The query does not state under what conditions of water balance the urinary specific gravity of 1.011 was obtained; if the specimen was voided under conditions of relative dehydration, as in a renal concentration test, such low specific gravity is of the greatest significance and implies grave and alarming depletion of the renal functional reserve. No mention is made of the blood picture; it may be assumed, however, that a relatively severe grade of anemia existed with such extensive renal damage. Transfusion of blood rather than venesection might have prolonged his life temporarily (but only briefly), for the extensive renal arteriolar constriction and anemia are the major factors in aggravating renal failure. The kidneys require a liberal supply of oxygen; anything which diminishes the oxygen available to the renal parenchyma may precipitate acute renal failure and uremia when the renal reserve is grossly depleted. No mention is made of evidences of cardiac exhaustion despite the tremendously high diastolic tension.

Levels of systolic tension from 300 to 400 mm. of mercury are unusual but not extremely rare. Without exhaustive search it is impossible to state exactly the maximum arterial tension ever recorded. The diastolic tension is the more significant of the two, as regards both the height of the tension and its variability. In severe acute arterial spastic states (as in eclampsia) the diastolic tension has been observed above 200 mm. of mercury. There is no satisfactory correlation between the level of the arterial tension and the prognosis in individual instances; many factors are involved. The fixedness of the diastolic tension, for example, is more significant than the maximum level, for it reveals the extent of irreparable arteriosclerotic degeneration. Factors such as age, the duration

of the hypertensive arterial disease, the rate of its progression, the cardiac and renal functional reserves, the nature of the provoking etiologic factors and the inherent vulnerability of the patient (often partially revealed by the family history) must all be considered (Stieglitz, E. J.: Arterial Hypertension, *Arch. Int. Med.* 46:227 [Aug.] 1930).

Venesection, with the removal of from 200 to 500 cc. of blood, usually causes a temporary reduction of the arterial tension but is of little therapeutic value except in acute cardiac failure with increased venous pressure. In such instances the temporary relief gives the heart a short "breathing spell" and may turn the tide toward recovery of compensation. As the transient reduction of arterial tension following phlebotomy is usually followed by a further rise in the tension, the procedure in cases of cerebral accident is associated with definite risk.

Adequate diagnosis must include not merely the name of a disease but an understanding of its complex and multiple causation, an evaluation of the functional capacity of the injured structures (here the arterioles, kidneys and heart) and search for complicating disease processes. In the present instance renal function studies and blood examinations were needed. Evaluation of the renal functional capacity serves not only to clarify diagnosis but also to reveal the benefit (or lack of benefit) of therapeutic measures. The anemia of nephritis and/or severe hypertensive arterial disease is a most significant factor in the self perpetuation and progression of the disease.

Apparently nothing was done therapeutically for the nephritic element. There is no specific therapy for nephritis, but realization of the renal mechanisms for the secretion of urine points out two vital therapeutic indications: (1) correction of any anemia so that the kidneys may have as good a blood supply as possible (this frequently will also reduce the hypertension) and (2) a large fluid intake. The intake of water should be pushed almost to the limit of cardiac endurance, for the fundamental functional failure in nephritis is the inability of the renal secreting mechanism to concentrate the urine. Therefore, in order that the toxic solutes and metabolic debris may be adequately eliminated, it is imperative that a large volume of urine be secreted. From 3 to 5 liters of fluid daily is not excessive for uremic or preuremic patients, if it is consumed in small quantities at frequent intervals.

PROVOCATIVE PHENOMENON IN SYPHILIS

To the Editor:—What dose of arsphenamine should be used for a provocative test for syphilis? Authorities do not seem to agree. What is the time between the giving of the drug and the taking of blood for the Wassermann test?

ROY A. ZINK, M.D., Tulsa, Okla.

ANSWER:—Studies of the provocative phenomenon in syphilis so far carried out are inconclusive on three scores: (a) the dosage of the arsenical to be employed, (b) the proper time interval between tests after treatment and (c) the use up to this time of a qualitative rather than a quantitative serologic technic. Such information as is available indicates that in all patients with early syphilis and in the majority of those with late syphilis, the first injection of a therapeutic dose of an arsphenamine (e. g., arsphenamine 0.3-0.4 Gm., neoarsphenamine 0.45-0.9 Gm., mapharsen 40-60 mg. and so on) is followed within five to seven days by a quantitative rise in reagin titer, which falls to or below its original level by the fourteenth day after treatment.

The provocative test is of no value whatever as a determinant of "cure" in a patient who is seronegative following treatment, since the provocative phenomenon often fails to appear in individuals whose subsequent course includes definite progression or relapse.

Almost the only circumstance in which the provocative test is of value is for the confirmation of the diagnosis in individuals previously untreated, in whom the presence of syphilitic infection is suggested by a low titer reagin content of the blood; i. e., those in whom doubtful or weakly positive serologic tests are obtained. In such persons the administration of a therapeutic dose of an arsphenamine is often followed by a quantitatively measurable increase in reagin titer, and if such an increase occurs the diagnosis of syphilis may be regarded as confirmed.

The suggested procedure is: (a) a preliminary serologic test on a quantitative basis, (b) the intravenous administration of a therapeutic dose of any of the arsphenamines, (c) repetition of the quantitatively titered serologic test at forty-eight hour intervals for a minimum of from ten to fourteen days.

No reliance should be placed on the result of the tests unless the laboratory is prepared to furnish quantitative titrations.

MELANCHOLIA AND INCREASED LIBIDO

To the Editor:—A man aged 50 has complained for the past year of symptoms of involuntional melancholia, consisting of periods of extreme depression, crying spells, discouragement and even a desire for death. At the same time the libido has become increased, although physically the patient is unable to meet the demands of this excessive sexual desire. He shows a decided preference for the company of young people, both male and female, which is unusual for him. He imagines himself in love with a young girl employee, although he realizes that this is probably a manifestation of his increased libido. His insight into his condition is remarkably good. He shows no symptoms of any major psychosis. Physical examination and blood examination are negative. During the past year he has received theelin in oil, bromides and at one time benzedrine sulfate. The depression seemed to clear with the benzedrine sulfate temporarily but recently he has been getting worse. He is happily married, loves his wife and yet feels that his condition may break up his home. Recently he has contemplated suicide on several occasions. Will you please outline the best plan for the relief of his condition? Would local medications to the verumontanum have any effect in decreasing his sexual desire? If this is purely an involuntional state, which endocrines would you advise administering? Would ligation of the vas have any beneficial effect?

M.D., New Hampshire.

ANSWER.—This patient is evidently going through a period of depression and would perhaps best be treated away from his present environment in an institution where proper psychotherapeutic and medical methods would be employed. In addition, there should be adequate safeguards against any suicidal attempts or gestures. Such patients require planned psychotherapy, adequate exercises and occupational therapy, tubbing, and occasional small doses of barbital to ease the symptoms of depression. Ligation of the vas would not have any beneficial effect but, on the contrary, might even increase the causes for the patient's depression. Local medications to the verumontanum would only fixate this depression to the sexual sphere and thereby perhaps overemphasize the sexual component of the patient's illness.

"DENICOTINIZED" CIGARS AND CIGARETS

To the Editor:—I have had to give up tobacco but have heard of Carl Henry cigars and cigarettes, which are supposed to have had most of the nicotine removed. Can you inform me as to the facts?

R. W. Ford, M.D., Otego, N. Y.

ANSWER.—Although denicotinization is a laboratory possibility, no completely denicotinized product is yet commercially available. According to their own advertisements, Carl Henry cigars and cigarettes contain from 0.6 to 1 per cent of nicotine. The average popular brands of cigarettes on the market for which no special claims of denicotinization are made contain on the average 2 per cent and cigars about 1.7 per cent. Accordingly, three Carl Henry cigars or cigarettes contain about as much nicotine as do two ordinary ones. Any reliance placed on the processing leading to the consumption of more of the so-called 'denicotinized' products may therefore lead to a greater nicotine intake than if untreated brands were used.

QUININE IN LATE PREGNANCY

To the Editor:—What is the current opinion as to the use of quinine in small doses for several weeks prior to the onset of labor for the purpose of shortening the duration and decreasing the pain? Would there be any harm to the mother or the child, aside from the occasional idiosyncrasy to quinine, in administering the dihydrochloride in doses of 1 grain (0.065 Gm.) three times a day for about four weeks before the onset of labor?

MICHAEL BALLIN, M.D., Chicago.

ANSWER.—There has been a general impression that small doses of quinine given to a patient during the last month or so of pregnancy will result in a shorter and less painful labor. This practice has found little vogue in this country. Recently Smith reported a small group of cases in which the patients received 0.1 Gm. (1½ grains) of quinine dihydrochloride three times a day during the last three weeks of their gestation with favorable results.

Pharmacologically, quinine is a poor and ineffective oxytocic drug. It may, however, act as a general tonic, thereby having some influence on the uterus. There are a number of undesirable effects from the use of this drug, in addition to the idiosyncrasy on the part of the patient which has been mentioned. Occasionally a baby succumbs in utero during a quinine induction of labor, even though only small doses of the drug were used and at autopsy nothing is found to account for the fetal death. Furthermore, a recent publication traced the origin of nerve deafness in children to the administration

of quinine to their mothers. These undesirable effects and the lack of clearcut proof that the administration of small doses of quinine late in pregnancy has any favorable results on the labor make it inadvisable to administer the drug to patients in a routine manner.

GONORRHEA AND ENLARGED PROSTATE IN ELDERLY MAN

To the Editor:—A man aged 63 has an enlarged middle lobe of the prostate with a 4 ounce urinary retention. October 22, 1937, he contracted an acute gonorrheal infection and a short time later a cystitis. There were no other complications. The urethral discharge cleared up in about a month but both glasses remain cloudy and an examination of a centrifuged specimen of the urine shows pus and gram-negative intracellular diplococci, which I assume are from the bladder. He has no frequency and gets up only once at night. I have given him various urinary antiseptics, including sulfanilamide in large doses. I am now giving him foreign protein injections intramuscularly. I have also massaged his prostate, which is normal in size. Have you any suggestions?

M.D., Connecticut

ANSWER.—The administration of urinary antiseptics, including sulfanilamide, will probably not benefit this patient much, nor will foreign protein injections help much. These statements are based on the fact that the patient is 63 years of age, has a large middle lobe of the prostate, and 4 ounces of residual urine and pus in the urine.

If the organisms are gonococci and the patient has a gonococcal infection of the bladder, the persistence of the gonococci in the urine is due no doubt to the fact that the patient has an obstruction at the bladder neck with resulting residual urine. A complete urologic study is desirable, including routine roentgen study of the entire tract to rule out the possibility of stone. A set of intravenous pyelograms should be made in order that one may have an understanding of the pathologic condition of the upper urinary tract. Finally, careful study of the renal function should be carried out.

After these examinations have been made and if there are no contraindications, a transurethral resection of the prostate would be advisable.

SACCHARIN IN DIABETES

To the Editor:—Please give the indications for the use of saccharin in diabetes.

M.D., Louisiana.

ANSWER.—Properly speaking, there are no indications for the use of saccharin in the treatment of diabetes, for this substance has no inherent therapeutic properties. However, it is commonly used to impart sweetness to foodstuffs in place of the sugars. In this way it may be of therapeutic value indirectly by rendering a low carbohydrate diet more palatable and removing the temptation to "cheat" on the diet. The sweet taste of saccharin is not strictly comparable to that of dextrose or sucrose. Even a slight excess of saccharin may introduce an objectionable bitter after-taste. It should therefore be used in moderation, with the purpose of counterbalancing excessive sourness or bitterness in foods rather than of making them really sweet.

REMOVAL OF TOBACCO STAINS FROM TEETH AND SKIN

To the Editor:—What is the best procedure for removing tobacco stains from the teeth and cigaret stains from the fingers? Several patients have inquired and I have no satisfactory answer.

M.D., New York.

ANSWER.—Dentists remove tobacco stains from the teeth by scouring them with pumice. Some of them wet the powder with a small amount of hydrogen peroxide. Tobacco stains on the skin can be removed by rubbing with acetone.

REPEATED ORGASM

To the Editor:—A patient of mine relates the following sexual episode, and I am interested in determining its veracity in your opinion: He states that during intercourse he has an ejaculation and then is able to maintain an erection without the appearance of flaccidity. About ten or fifteen minutes after the first ejaculation active intercourse is repeated, with another ejaculation. Is this physiologically normal?

M.D., New York.

ANSWER.—Yes.

SPECIAL BOARDS

Examinations of *Special Boards* were published in THE JOURNAL, October 8, page 1401.

Maine July Report

Dr. Adam P. Leighton, secretary, Maine Board of Registration of Medicine, reports the written examination held at Augusta, July 5-6, 1938. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Nineteen candidates were examined, eighteen of whom passed and one failed. Seven physicians were licensed by reciprocity. The following schools were represented:

| School | PASSED | Year Grad. | Per Cent |

Colorado July Examination

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports the written examination held at Denver, July 6-8, 1938. The examination covered eight subjects and included 163 questions. An average of 75 per cent was required to pass. Fifteen candidates were examined, thirteen of whom passed and two failed. The following schools were represented:

| School | PASSED | Year Grad. | Per Cent |
|---|--|------------|----------|
| Northwestern University Medical School..... | (1937) | 81 | |
| University of Illinois College of Medicine..... | (1938) | 86 | |

* Examined in medicine and surgery.

Vermont June Report

Dr. W. Scott Nay, secretary, Vermont State Board of Medical Registration, reports the written examination held at Burlington, June 15-17, 1938. The examination covered twelve subjects and included ninety questions. An average of 75 per cent was required to pass. Twenty-one candidates were examined, all of whom passed. Two physicians were licensed by endorsement. The following schools were represented:

| School | PASSED | Year Grad. | Per Cent |
|--|---------------|------------|----------|
| Georgetown Univ. School of Medicine..... | (1932) 85.2,* | (1934) | 88 |

Book Notices

The Horse and Buggy Doctor. By Arthur E. Hertzler, M.D. Cloth. Price, \$2.75. Pp. 322, with 10 illustrations. New York & London: Harper & Brothers, 1938.

Now and then a book by a physician is selected to be the "book of the month" by those who make these choices. This autobiography by Arthur E. Hertzler is well chosen, for it is so human, so vital, so sensitive, so reasonable and so direct that it captures the interest, if not the complete sympathy, of those who read it. Dr. Hertzler has seen life at first hand. As nearly, apparently, as it can be done he has combined the personality of the old family doctor with the science and knowledge of the modern physician. He has been successful, but not beyond his merit, and he has been happy because he has done the work that he wished to do without considering too much what others thought about him and his work. Although untrained in psychoanalysis, he knows his people and he probably gets results like those achieved by psychoanalysts and psychologists simply because he does know his people. There has seldom been a work published by a physician which will strike a more sympathetic note among doctors, simply because Hertzler speaks freely and with insight. Some of his aphorisms will be quoted for years to come. A few examples may suffice.

Regardless of what the old doctor was able to accomplish in a therapeutic way, the sense of security inspired by the doctor's arrival affected the patients favorably.

The ability of the old type doctor was enhanced because he remained at the patient's bedside until his suffering was relieved, even though it required many hours to achieve that end.

It may be said that one of the most important problems of the family doctor is to determine when or if the patient should consult a specialist and select a reliable one for him.

One need have no compunction in calling certain types of patients "female complainers," for that is just what they are.

Operative treatment is the spectacular part of the doctor's life.

Human nature being what it is, if any one does something that sticks his head above his environment he invites the inevitable brickbat.

In the hospital field, standardization has sought to compel us of the typical prairie states to adopt the ideas of the more wealthy areas. The extravagant architecture naturally has resulted in vastly increased costs of hospital care, which in recent years has so vastly concerned those who have brought it on themselves. They should have thought of that before they started their building program. If one lives in a palace when he is well naturally he feels that he must be sick in one. Those of the common herd who think marble is used only for gravestones do not miss it when they go to a hospital.

To the doctor the human being is primarily an animal actuated by the fundamental urges common to all animals.

Anger as a disturber of health is a less potent factor than fear but as such is often overlooked.

Public service in large measure is able to protect the public from infectious disease whether it wishes it or not. The cure of individual disease is much more difficult to force on the patient. The difficulty, therefore, lies not in the availability of adequate medical service but in the intelligence of the patient to use it. The term intelligence must be given a broad application.

Guinea Pigs and Bugbears. By G. L. Eskew. Cloth. Price, \$1.50. Pp. 269, with 21 illustrations. Chicago: Research Press, 1938.

This book is admittedly promulgated for the purpose of dispelling fears and cautions which the public may have developed as a result of the propaganda of such organizations as Consumers' Research and Consumers' Union. One of the principal contentions of the author is that these organizations are not qualified to give advice, and, so far as that applies to medical information which has appeared to date in some of the publications of those organizations, the reviewer agrees. It must be stated, however, in all fairness that these organizations have probably never wandered any farther from fact than this author does in condemning them. A reprint of a roentgenogram of a pathologic colon is reproduced from a publication by Consumers' Union and compared with an anatomic drawing which the author labels a normal healthy colon. Such colons, as depicted in the roentgenogram, do exist, while the drawing which the author labels a normal healthy colon merely indicates comparative anatomic relationships. He claims that the title of the text "100,000,000 Guinea Pigs" is unjustified because "Everything that can be tested is tested before it is manufactured [sic] and offered to the public. . . . Manufacturers do not wait to observe the effects of their medicines upon human beings. It has already been worked out." One who attempts to act as an authority in these matters should be

fully familiar with the fact that a great many preparations which are placed on the market are not pretested. As a matter of fact this text contains reference to the Elixir of Sulfanilamide episode, but the author dismisses it lightly as follows: "The worst that can be said is that it was an error. The manufacturers admit the error, and have in numerous instances made financial amends, which is the best they can do. . . . The law however should provide. . . ." Thus does one who glorifies manufacturers excuse one of them for an error which caused deaths by the score. The author decries certain misinformation released by consumers' organizations, but some of his own statements are equally misinforming. His subheading for the chapter on Proprietary Medicines and Cosmetics—"They've Got to Be Good!" is mere wishful thinking; such chapter headings as "Read Schlink and Be Leery" are funny but far less amusing than some of the text of the book. The author discusses the American Medical Association in part as follows: "Some proprietary medicines which have long had a large sale, have been accepted by the consumer, and found to be efficacious in relieving minor afflictions, are, and have always been classed as nostrums by the Association. The reason is not far to seek. Self-medication, or any product that makes self-medication possible . . . deprives the doctor of some revenue, so from that angle there is naturally some objection to it regardless of whether the particular medicine is more profitable or satisfactory to the consumer than the service of a doctor." These statements display such ignorance that they do not deserve consideration. Is it possible that the author knows nothing about the medical profession's active part in disease prevention and public health? The dangers of self-medication are not detrimental to the doctor's income but rather to the health and welfare of the patient. The American Medical Association has led the way in the fight against dangerous "patent medicines" so that actually self-medication may be somewhat less hazardous than at one time, but it is still frequently disastrous. The author is apparently unaware of the fact that the Council on Pharmacy and Chemistry of the American Medical Association permits advertising directly to the public of certain types of its accepted products when it is in the interest of the public to do so, as for example antiseptics. There is a chapter on "How the Government Protects Us" which cites seizures under the violations of the Food and Drug Act. The book concludes with two chapters, one on "Big Business" which ends with a section on "How Much We Owe to 'Big Business,'" and a final chapter which is a boost for "The Druggist—Your Good Friend." Errors in this volume do not inspire confidence, and misrepresentation of fact indicates unfamiliarity with the subjects. Some of the statements are as far from reality as the author's "bugbear" which looks like a cross between a bear and a grasshopper. It may be granted that consumers' protective organizations have certain faults, but there is no excuse for the promotion of the utopian opinion of commercial altruism which this author seems to hold. It is interesting to note the comment of some of the "Big Business" which he glorifies. *Drug and Cosmetic Industry* concludes its review of this book as follows: "As is often the case, cosmetics, drugs and foods may suffer more from the intemperate defenses of friends than from attacks of their avowed enemies."

Les acquisitions nouvelles de l'endocrinologie. Par H. Rivolt. Third edition. Paper. Price, 45 francs. Pp. 264, with illustrations. Paris: Masson & Cie, 1937.

The first edition of this interesting work appeared in 1931. In opening the present edition the author remarks on the immense progress achieved in endocrinology during the decade since his first publications in the field. With characteristic French pride he refers to the satisfaction from the proportionately large contributions, physiologic, biochemical and clinical, made by French physiologists, physicians and surgeons. Ten years ago theories were prominent, their bulk now gratifyingly reduced or replaced by ascertained relevant facts. The first fifty-seven pages expound developments in parathyroid endocrinology. From the fatal tetany formerly inevitable in laboratory dogs after parathyroid removal, valuable and gratifying control of experimental results have been secured by ascertaining the mutual relations and interchanges of the calcium and

the phosphorus content in the blood. American physiologists are credited with "profound analyses of the mineral interchanges involved in studying minutely the influence of food regimens upon the phospho-calcic exchanges in tetanous animals." The eighth and final chapter, of 59 pages, points out the momentous developments in endocrinology of the hypophysis, with their significant influence on the thyroid. Intervening chapters set forth adrenal, pancreatic, thymic endocrine problems and experiments, together with those of the sex glands, male and female. Much discussion of Addison's disease occurs in connection with cortico-adrenal discoveries. The efficient salt solution therapy evolved was first published by Professor Achard and Rivoire in the author's first edition, 1931. Space is also given (p. 98) to "a recent discussion in Chicago in the Central Society of Clinical Research, where Snell and Kepler on the one side and Hoffmann and his pupils on the other reported uniformly favorable results obtained with the cortical extract of Kendall, and that of the Wilson Laboratory. Kendall, however, had never observed cortical resistance to his extract in Addison's disease." Rivoire declares impartially for the two extracts, adding a third from Amsterdam and regretting the absence of an "active" French preparation. No bibliography appears in this work; authors are referred to merely by name, though some are dated, as "Zondek, 1931," "Iscovesco, 1912," "Smith, 1921."

Surface and Radiological Anatomy for Students and General Practitioners. By Arthur B. Appleton, M.A., M.D., Professor of Anatomy in the University of London, William J. Hamilton, M.D., B.Ch., D.Sc., Professor of Anatomy in the University of London at the Medical College of St. Bartholomew's Hospital, London, and Ivan C. C. Tchaperoff, M.A., M.D., B.Ch., Assistant Radiologist at St. Thomas's Hospital, London. Cloth. Price, \$5.50. Pp. 311, with 338 illustrations. Baltimore: William Wood & Company, 1938.

The authors endeavor to provide an introduction to the study of anatomic features which are accessible to examination in the living subject, and to the usual methods of physical examination they have added radiology. By the extensive use of illustrations in this book they were able to coordinate radiologic anatomy with those features which can be determined by external examination and with those other details which can be determined only by dissection. The book is arranged in sections corresponding with the parts in which the body is usually dissected, and some blank pages for notes have been included. Some general consideration is also given to radiologic technic, which they believe necessary for the interpretation of the roentgenograms. They omit detailed descriptions of the attachments of individual muscles but emphasize the coordinated production of movement and maintenance of posture. The book shows the surface contours in relation to the underlying structures to elucidate especially the more difficult radiologic appearances. The roentgenograms have been reproduced as negatives in view of the general practice of examining original roentgenograms in this form.

Workbook in Elementary Diagnosis for Teaching Clinical History Recording and Physical Diagnosis. By Logan Clendening, Professor of Clinical Medicine, University of Kansas. Cloth. Price, \$1.50. Pp. 167, with illustrations. St. Louis: C. V. Mosby Company, 1938.

According to the author, this book is intended as a workbook in elementary diagnosis covering a course for sophomore medical students. The student should readily acquire the routine of history recording and learn the methods of physical examination on reading this textbook because the subject is presented simply. There are a few errors which might be corrected; for example, it is definitely an error to define a thrill as just what the name implies—it is a grating feeling and a crepitation and at the same time to describe "a thrill as similar to a feeling as when your hand is on the neck of a purring cat." "Point of Maximum Impulse (PMI) is not the apex but is caused by the impact of the flat of the ventricle" should be more definitely referred to the left ventricle and the "flat" omitted. In the description of palpation of the abdomen it is regrettable to note a failure of the author to begin with the palpation of the normal abdomen and the failure to mention the necessity for gentleness during examination in the normal and abnormal condition of the abdomen. The chapter devoted to examination of children and infants is commendable. The author has unquestionably succeeded in making the entire text elementary. It is questionable whether so ele-

mentary a presentation for sophomore medical students is necessary. The pen and ink drawings, while beautifully executed and in keeping with the idea of a primer, do not convey as much as photographs. The exercises at the end of the book complete the idea of an elementary textbook but it is questionable whether a sophomore student will profit by an exercise such as naming twenty diseases in which there are enlargements or masses in the neck. This book is distinctly pedantic in type and therefore is not in keeping with the more liberal trend in medical teaching.

How to Live: Rules for Healthful Living Based on Modern Science. By Irving Fisher, LL.D., and Haven Emerson, M.D., Professor of Public Health Practice, Columbia University. Prepared in collaboration with the Hygiene Reference Board of the Life Extension Institute and the Advisory Board of the Vitality Records Office. Twentieth edition. Cloth. Price, \$2.50. Pp. 422, with illustrations. New York & London: Funk & Wagnalls Company, 1938.

This volume is now in its twentieth edition. This edition is dedicated to Dr. Eugene Lyman Fisk, who was co-author in all earlier editions. In the preparation of the new edition members of the reference board collaborated, so that it may be presumed that all of them take some of the responsibility for what is contained in this volume. There are also a considerable number of appendixes devoted to specific subjects in which individual authors take the responsibility. Unfortunately, the work has not been sufficiently revised to eliminate several ridiculous statements which appear in the text. For example; In the illustration between pages 8 and 9 it is said that the wearing of shoes with pointed toes leads to anemia, indigestion and poor circulation. On page 38 it is said that an ample diet includes raw fruits, raw nuts, raw greens and dairy products, and that such a diet provides every essential of complete nutrition for the average person. On page 42 it is said that the proteins of meat are less perfect than the proteins of nuts and greens. On page 56 the suggestion is made that the average person obtain litmus paper from a drug store and test his urine to see if it is acid or alkaline; and, indeed, it is urged that he do so to keep his urine neutral—a suggestion which is certain to create a good many urinary hypochondriacs. On page 58 appears the strange notion that canned foods are practically devoid of vitamins and that when people camp out and live on canned foods they become vitamin hungry so that they develop a special craving for vitamins. Where is the scientific evidence to support this notion? Also a holdover from a period of superstition in diet are those sections of the book concerning the eating of meat and the hygiene of the colon. These special views are not held by the majority of scientific physicians. Pages 396-402 are occupied by testimonials in favor of some of the peculiar notions expressed in the pages that have been especially mentioned. The chapter dealing with alcohol and tobacco is full of nonsense. Fortunately the articles which appear in the appendixes and which constitute about half the book may be considered as individual contributions for which only their authors are responsible. There it becomes clear what part has been played in the adoption of some of these views by the proponents of certain special concepts in the field of health.

Previous editions of this book have sold almost 450,000 copies. Perhaps by the time the twenty-first edition is reached a real revision and modernization may be provided.

Chemistry of the Brain. By Irvine H. Page, A.B., M.D., Hospital of the Rockefeller Institute for Medical Research, New York. Cloth. Price, \$7.50. Pp. 444. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1937.

This volume represents a summary of the present state of our knowledge concerning brain constituents and their metabolism. There are extended and valuable references, particularly to the more recent investigations in the general field of intermediary metabolism, so that the scope of the work is considerably greater than its title would indicate. There is an excellent historical introductory chapter, followed by a more extensive survey of the chemistry and metabolism of various brain constituents. A comprehensive chapter on brain oxidations has been contributed by Dr. J. H. Quastel of the Cardiff Mental Hospital. The purely chemical aspects of brain constituents are treated briefly, the emphasis being on their correlation as far as possible with metabolic function. The clinical aspects of the problem are not neglected and the book

should prove of interest not only to the laboratory investigator but to the clinician as well. The organization and critical interpretation of the large amount of data included in the book is a task of considerable difficulty, and it is doubtful whether the present status of our knowledge of many of the topics treated is sufficient to permit a treatment of the data that would be universally acceptable. On the whole, however, the treatise represents a valuable contribution to biochemical and biologic literature.

Medical State Board Questions and Answers. By R. Max Goepff, M.D. Seventh edition. Cloth. Price, \$5.50. Pp. 644. Philadelphia & London: W. B. Saunders Company, 1938.

This book offers concise answers to the actual questions asked at state board examinations in all the forty-eight states and by the National Board of Medical Examiners. Since 1929, when the previous edition was published, there have been so many advances in medicine that a new edition was considered advisable. The changes were so numerous that the type was entirely reset. The author was assisted in this work by Dr. Frederick S. Baldi in medical jurisprudence, Dr. Abraham Cantarow in bacteriology, Dr. Calvin M. Smyth Jr. in surgery and gynecology, and Dr. Robert P. McCombs for the selection of material. The questions and answers are arranged under the general headings of anatomy, physiology, physiologic chemistry, pathology, bacteriology, materia medica and therapeutics, practice of medicine, surgery, obstetrics and gynecology, hygiene and medical jurisprudence. There is an extensive index, which is an indispensable feature of the book if it is to be used as a reference volume. In their effort to be concise, perhaps the authors occasionally trimmed some of the answers too closely. On page 24 is the question Name the endocrine glands. The answer given is "spleen, suprarenal bodies, glandulae caroticae (O. T. intercarotid bodies), thyroid and parathyroid, thymus, glomus coccygeum."

Practical Clinical Gynecology. By Henry C. Falk, M.D., F.A.C.S., Clinical Professor of Gynecology, New York University College of Medicine. Cloth. Price, \$5. Pp. 393, with 190 illustrations. New York: American Journal of Surgery, Inc., 1938.

This volume is apparently intended to convey a smattering of gynecology to practitioners who have forgotten what they were taught in medical school. The book is written informally, with frequent use of questions and answers. Much of the writing is loose. Many of the principles enunciated are entirely contrary to the best gynecologic practice of today. There is no evidence of the author's familiarity with many important gynecologic studies published in the last ten years. The illustrations are in no way impressive. The scope of the work is exemplified by the chapter on carcinoma, which in a scant fourteen pages covers (after a fashion) the cause, course, signs, symptoms, histologic diagnosis, clinical diagnosis and treatment of carcinoma of the uterus (cervix and fundus). The treatment of carcinoma is described in two sentences. Retroperitoneal erysipelas is mentioned, but there is no discussion of dropsy of the ovary. The volume is not recommended for nurses, undergraduate students, postgraduate students or gynecologists. It is poorly organized, incomplete and in many places unsound.

Thirty Years After: The Story of the Class of 1908, Medicine, of the University of Pennsylvania in the Thirty Years That Have Elapsed Since Leaving the Medical School [Including Portraits]. Data compiled by J. H. Musser, M.D. Cloth. Pp. 114, with illustrations. New Orleans: Wetzel Printing, Inc., 1938.

This is the story of a class which graduated thirty years ago from the University of Pennsylvania School of Medicine. There is a brief biography accompanied by a picture of each living member of the class of 1908, of which there are 111, thirty-three of the members having died since graduation. There is also a statistical analysis which brings out some interesting facts. Four of the members of the class of 1908 have not married; ninety-two married men of the class have a total of 181 children, or a little less than two children per marriage. Of these 181 children, forty-two, or 25 per cent, are either already doctors or are going into medicine. At the end of ten years the average income of sixty-four men in the class was \$6,787. At the end of twenty years the average income of sixty-one men of this class was \$15,803. At the end of thirty

years after graduation the average income of sixty-six men was \$13,157. Nearly all the members reported a decrease in their financial returns from practice at the end of thirty years as compared with the end of twenty years. The author further analyzes the financial returns of the class with regard to whether they were general practitioners or specialists. The class has quite a remarkable teaching record, twenty-four of the 101 who answered this part of the questionnaire having obtained the rank in medical schools of either associate, assistant or full professor. Only nine of the living members of the class, however, are listed in "Who's Who." Among the hobbies and recreations, golf heads the list with thirty-six, tennis claims eight, baseball one, polo four, stamp collecting six, photography four, bridge four and poker one. There is a list of the deceased members of the class with brief data obtained chiefly from the obituary columns of *THE JOURNAL*.

A Text-Book of Bacteriology for Dental Students. By Arthur Bulleid, L.R.C.P., M.R.C.S., L.D.S., Dental Surgeon and Lecturer in Special Bacteriology to the Dental School, Guy's Hospital. Second edition. Cloth. Price, 15s. Pp. 207, with 77 illustrations. London: William Heinemann, Ltd., 1938.

The scope of this book is limited, although the author hopes "that it is comprehensive enough to give the student an insight into general bacteriology, with special application in his own sphere, viz.: the mouth." The size and content hardly warrant this claim and it is recommended rather as a supplement to the more comprehensive textbooks of bacteriology in rather general use. Technical methods and culture mediums are adequately covered; the portion concerning those specially adapted for use in studying the oral flora is highly commended. Pathogenic bacteria are disposed of in two chapters and the same amount of space is given to the subjects of immunity, vaccines and antisera. The section on the original bacteriology of caries has a number of faults. In it the author has failed to draw a sharp line between the past and the present. The inclusion of lengthy descriptions of organisms such as *B. gingivae pyogenes* and *B. plexiformis* taken from the works of Miller and Goadby is hardly warranted, since it is not possible to reconcile these names and descriptions with those used in modern textbooks on determinative bacteriology. The chapter on blood examinations and cell counts is probably out of place in a textbook on bacteriology.

Psychiatric Nursing. By William S. Sadler, M.D., Chief Psychiatrist and Director, The Chicago Institute of Research and Diagnosis, Chicago. In collaboration with Lena K. Sadler, M.D., Associate Director, The Chicago Institute of Research and Diagnosis, and Anna B. Kellogg, R.N., Chief of Nurses, The Psychiatric Clinic of the Chicago Institute of Research and Diagnosis. Cloth. Price, \$2.75. Pp. 433, with 19 illustrations. St. Louis: C. V. Mosby Company, 1937.

The book is divided into major chapters concerned with the history of psychiatry, the anatomy of the nervous system, an extensive chapter on considerations of neuroses and psychoses, the chapters dealing more specifically with nursing of various cases. Although the chapters on the neuroses are extensive, the classification of them is quite confusing and the various types overlap one another a great deal. The mechanisms are discussed from a rather simple psychobiologic point of view with a good deal of common sense. The psychoses are discussed along the orthodox lines. The presentation of the material is quite simple and undoubtedly can be easily absorbed by the average nurse. The last chapters of the monograph are very satisfactory. In the special problems of psychiatric nursing the author covers extensively the various emergencies and problems which come to the attention in treatment of psychiatric cases. There is a valuable chapter on therapy as used by a nurse and there is an excellent chapter on the personality of a nurse in the relation to the patient. On the whole this is a satisfactory manual for young women interested in psychiatric nursing.

Illustrations of Anatomy for Nurses. By E. B. Jamieson, M.D., Senior Demonstrator and Lecturer, Anatomy Department, University of Edinburgh. Paper. Price, \$3. Loose-leaf. 62 plates. Baltimore: William Wood & Company, 1938.

This volume is a condensation of the book called "Illustrations of Regional Anatomy" which has been prepared for doctors and medical students. Sixty-two of the plates from the larger book are included in the special volume for nurses.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Administration of Anesthetics by Nurse Under Direction of Dentist.—The appellee, a dentist, brought this suit in the superior court of Maricopa County, Ariz., against the state of Arizona and its attorney general, and the county attorney of Maricopa County, in their official capacities, for a declaratory judgment to determine his right to employ a nurse anesthetist. He alleged that in his practice it was frequently necessary to give a patient a general anesthetic and that he desired to employ a registered nurse, who had taken a prescribed course of anesthesia at a hospital in good standing, to administer the anesthetic under his direction and in his immediate presence. A question had arisen, however, as to whether such administration by a registered nurse was lawful and he desired an opinion from the court with respect to the matter. The superior court gave judgment to the effect that the course of conduct which he intended to follow was lawful, and the state appealed to the Supreme Court of Arizona.

The Arizona law regulating the practice of registered nurses contains the following provision:

A registered nurse may administer anesthetics under the direction of and in the immediate presence of a licensed physician or surgeon, provided such nurse has taken a prescribed course of anesthesia at a hospital in good standing, or is a graduate in the science of anesthesia from some recognized school or college.

The specific question considered by the court was whether a dentist, duly licensed to practice dentistry, was a "licensed physician or surgeon" within the meaning of the section just quoted, or whether for the purpose of that section these words mean a person who is licensed to practice medicine generally. The dental practice act, enacted in 1935, the court pointed out, for the first time expressly authorized dentists, in the practice of dentistry, to administer anesthetics. Before that time there was grave doubt whether under the law a licensed dentist could legally do so and it was the general practice, when such an administration was necessary, to call in a regular physician. It was clear to the court that the reason for the express inclusion in the 1935 dental act of the administration of anesthetics in the course of dental surgery as one of the things which a dentist was expected and permitted to do as a part of the regular practice of his profession was to remove any possible question as to his right to do so. There could be no question, therefore, that if the dentist in the present case himself, or any other licensed dentist, desired to administer an anesthetic to a patient, as a part of dental practice, they would be fully within their right under the law. It was contended however that while a dentist may administer the anesthetic himself, he may not permit a registered nurse to do it under his direction and in his immediate presence.

If, continued the court, a limited meaning is given to the words "physician or surgeon" as used in the law regulating the practice of nursing, the dentist in the present case was not a physician or surgeon within such meaning and therefore could not use a registered nurse to administer an anesthetic. But the legislature by the dental practice act of 1935 expressly gave to dentists the right personally to administer such treatment. Necessarily, by so doing, the legislature determined that a licensed dentist is fully qualified to administer an anesthetic in dental operations, which means that he knows not only how but when to give it. A licensed physician and surgeon can know no more, in the opinion of the court. To hold then that a qualified nurse may administer anesthetics in a dental operation under the direction of one man, when she may not under that of another who is equally qualified to direct her, would be to assume that the legislature had meant to permit one class of practitioners to do a certain thing, while prohibiting another class, equally qualified so far as the protection of the public health is concerned, from doing that

same thing. To give the section in the nursing practice act that meaning would be to give a practical monopoly, the court thought, of the administration of anesthetics in dentistry to licensed physicians and surgeons and thus render the act invalid as an exercise of the police power. To hold, on the other hand, that the word "surgeon" as used in the nursing act includes a "dental surgeon" would make it a proper and legitimate exercise of that power. Under such circumstances, the court pointed out, every rule of statutory construction required that it be given the constitutional, rather than the unconstitutional, meaning. It was the opinion of the court, therefore, that registered nurses in Arizona may administer anesthetics under the direction and in the immediate presence of a licensed dental surgeon for the purpose of assisting in any of the operations which such surgeon is authorized to perform. The judgment of the superior court was affirmed.—*State v. Borah (Ariz.)*, 76 P. (2d) 757.

Attorneys: Disbarment for Soliciting Personal Injury Cases Through Physicians.—On the petition of the Queens County Bar Association, disciplinary proceeding was brought in the supreme court of New York, appellate division, second department, against the defendant attorney, charging him with soliciting negligence cases or personal injury cases through physicians, policemen and others and paying such persons for procuring retainers for him. The court held that the records showed that the defendant had not only engaged in the activities charged but had resisted the charges and testified falsely. The defendant, said the court, was guilty of flagrant violations of duty as an attorney and was no longer entitled to engage in the practice of law. Accordingly, the court disbarred the defendant and ordered his name struck from the roll of attorneys.—*In re Glickman (N. Y.)*, 1 N. Y. S. (2d) 885.

Malpractice: Liability of Naturopath and Nurse for Burns Due to Diathermy Treatment.—The plaintiff was suffering from a painful swelling in the muscles of the right side of her neck and consulted the defendant naturopath. After examining the plaintiff, the naturopath prescribed a diathermy treatment, which was administered by the defendant nurse, an office assistant of the naturopath. As a result of the treatment, the plaintiff sustained a superficial burning and blistering of the skin over a considerable portion of her abdomen and a deep third degree burn about 3 inches in diameter in and around her umbilicus. She sued the naturopath and his nurse for damages. The trial court gave judgment against the naturopath but directed a verdict for the nurse, on the ground that she was not personally liable for the results of her negligence, if any, in the operation of the diathermy machine. The plaintiff excepted to the action of the trial court in thus instructing the jury to return a verdict for the nurse and appealed to the Supreme Court of Oregon.

On appeal, the nurse contended that the complaint did not state facts sufficient to constitute a cause of action against her. The complaint, observed the court, charged that the defendants administered the treatment in a careless and negligent manner, and as a direct result of this carelessness and negligence the plaintiff sustained the injuries of which she complained. If a complaint contains general allegations of negligence and carelessness, the court said, it is not essential that the details be set forth in it. This was an action for malpractice and the cause of action alleged in the complaint was a tort. In *Wemelt v. Mount*, 134 Ore. 305, 292 P. 93, the plaintiff had been burned during the course of diathermy treatments administered by a lay employee of the defendant physicians. The court in that case said:

This act is one of tort and all the defendants who participated or are responsible for the act are liable severally.

The complaint in the present case was, in the opinion of the court, sufficient. The lower court practically found that the defendant nurse was negligent and that she was not liable for her negligence but that the naturopath was. But, said the court, the nurse was not relieved from liability for her negligence because she was acting under the direction of her superior, the naturopath. In certain instances a nurse or office assistant of a physician might innocently injure a patient

without knowledge that her conduct would result in such injury. In the present case, however, the testimony tended to show that the nurse was fully aware of the results that follow the application of excessive current. A person who operates an x-ray or similar electrical appliances used in healing is required to use that degree of care, diligence and skill ordinarily possessed by similar operators in similar communities. The rules governing the duty and liability of physicians and surgeons in the performance of professional services are applicable to practitioners of the kindred branches of the healing art, such as dentists, oculists and manipulators of x-ray machines and like apparatus.

In the opinion of the Supreme Court, therefore, the trial court erred in not submitting the case as to the nurse to the jury. The judgment of the trial court in this respect was reversed and the cause remanded for further proceedings.—*Wood v. Miller et al. (Or.)*, 76 P. (2d) 963.

Drugs: Gauze Bandage a Drug Under the Federal Food and Drugs Act of 1906.—The claimant shipped packages of gauze bandages from Connecticut to a consignee in New York City. The bandages were in small packages contained in larger cartons, which were labeled, as were the small packages, to the effect that the gauze was sterilized. Each small package bore also a guaranty stating that the product had been "scientifically prepared for surgical use under the most sanitary manufacturing conditions." The gauze was not, however, sterilized or fit for surgical use but contained "living bacteria consisting of gram-positive sporeforming bacilli and nonspore-forming bacilli, gram-positive and gram-negative bacilli, capable of growing aerobic conditions and anaerobic bacteria." The shipment was seized under the federal food and drugs act and a libel proceeding filed in the district court for the southern district of New York to have condemned and declared forfeited the forty-eight packages comprising the shipment. The district court entered a decree of condemnation and forfeiture and the claimant appealed to the United States circuit court of appeals, second circuit.

The question on appeal was whether such a substance as a gauze bandage was within the scope of the federal Food and Drugs Act and so subject to seizure and forfeiture. That act, in section 6, defines the term drug as follows:

The term "drug," as used in sections 1 to 15, inclusive, of this title, shall include all medicines and preparations recognized in the United States Pharmacopeia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation, or prevention of disease of either man or other animals.

If a gauze bandage is within the act at all, the court said, it must fall within its purview as a "substance . . . intended to be used for the cure, mitigation, or prevention of disease of either man or other animals." In the opinion of the court, a gauze bandage was such a substance. The claimant argued, however, that the meaning of the word "substance" must be held to be somewhat narrowed, under the principle of ejusdem generis, by words used in the statute in connection with it. But the application of that principle, the court said, did not help the claimant's cause in this particular case. Among those things recognized in the United States Pharmacopeia as "preparations" are absorbent cotton and adhesive plaster made by spreading the adhesive on cotton cloth. This recognition of absorbent cotton, a substance generally similar in composition and use to gauze bandage, sufficiently indicated to the court that the latter, while not itself recognized, was of a kind not dissimilar from a substance that was recognized. That made it, the court thought, exactly the sort of thing Congress must have intended to include in the general language which was put there for the very purpose of making the statute cover more substances of the kind mentioned than were actually recognized in the Pharmacopeia or National Formulary.

The act, continued the court, was passed to prevent injury to the public health. It should be given a fair and reasonable construction to attain its aim. Gauze bandages, clearly intended for surgical use, are a menace to the public health when misbranded to show that they are sterilized. In the present case the gauze bandages were not fit for the use for which their labels

falsely represented them to have been prepared and so were subject to condemnation and forfeiture.

The judgment of the district court against the claimant was affirmed.—*United States v. 48 Dozen Packages, More or Less, of Gauze Bandage Labeled in Part Sterilized*, 94 F. (2d) 611.

Malpractice: Burns from Hot Pack-Off Placed on Patient's Abdomen.—The defendant, a physician, performed an abdominal operation on the plaintiff during the course of which a hot pack-off was placed on the patient's abdomen and a burn resulted. She thereafter sued the defendant in the superior court, Androscoggin County, Maine, but subsequently the case was withdrawn from the jury and, with the consent of the parties, presented to the Supreme Judicial Court of Maine for determination.

From the evidence, the court said, a jury could properly infer that while the patient was under the influence of ether and still on the operating table, the pack-off was laid on her abdomen and a burn resulted. There was nothing, however, warranting a finding that the defendant placed the pack-off on his patient's abdomen. Nor was there any showing that in the exercise of that degree of care and skill required of him, with constant guard against possible complexities, he could have discovered the pack-off. Its application did not appear to have been known to him until his patient was back in her own hospital room, when the fact that she had been burned was called to his attention. The presence of the pack-off was quite as likely to have been due to the fault of others, the court said, as to any act, either of commission or of omission, of the defendant. Strikingly similar to the present case in essential principles, the court pointed out, was *Guell v. Tenney*, 262 Mass. 54, 159 N. E. 451. In that case, one of tort against a surgeon who, at a private hospital, performed an appendectomy and allegedly did not remove a sponge before closing the incision, the court said:

The nurses who were present at the operation were employed by the hospital. There was no evidence to show that any of the persons present at the operation were servants or agents of the defendant. . . . It may fairly be inferred that, in the performance of an operation of this character in a hospital, nurses are commonly present to assist the operating surgeon. . . .

As there was no evidence that the nurses or other persons present and assisting were servants or employees of the defendant, he cannot be held responsible for [any negligence on their part].

So in the present case the court thought that the doctrine of respondeat superior did not apply and that the judgment should be for the defendant.—*Watson v. Fahey (Maine)*, 197 A. 402.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Chlorionepithelioma. H. B. Dowling, Mobile.—p. 64.*

*Atabrine as Malarial Prophylactic Agent: Experiment with Drug in a Region in Central Alabama. D. G. Gill, Montgomery, and M. Smith, Tuskegee.—p. 66.

Asthma: Treatment with Iodized Oil: Report of 103 Cases. J. F. Alison, Selma.—p. 68.

Atabrine as Malarial Prophylactic.—The efficacy of atabrine in preventing clinical attacks of malaria was studied in an area located in Macon County, Ala. The area was divided into two approximately equal and similar parts. To the inhabitants of one part Gill and Smith gave doses of 0.025 Gm. of atabrine to children and 0.15 Gm. to adults twice a week, while those of the other part received no prophylactic medication, thereby serving as controls. The atabrine given on two non-consecutive days of each week was instrumental in reducing the blood parasite index from 22.9 to 3.4 per cent over a period of five months—from June to November. During the same time the index of the control group decreased from 13 to 4.6 per cent. Atabrine was administered a maximum of forty-three times to the 726 persons in the prophylactic group, the average number of administrations per person being 36.6. The number of clinical attacks of malaria in the prophylactic group was twelve during the entire season, as compared with ninety-six clinical attacks in the control group not receiving atabrine. Of the twelve cases of malaria occurring in the prophylactic group, more than one half occurred in July. After July the incidence in the prophylactic group fell rapidly, reaching nil in October, while during this month eleven cases appeared in the control group.

Mortality of Merozoites in Infections with Plasmodium Cathemerium in Canaries. R. Hegner and Lydia Eskridge, Baltimore.—p. 299.

Common Duck as Convenient Experimental Host for Avian Plasmodium Fruma Wolfson, Baltimore.—p. 317.

Neonatal Mortality.—With a view to investigating the effects of the order of birth and the age of the parents on neonatal mortality, Yerushalmy studied the records of 2,563 infants who died before they were 1 month old out of the 82,140 infants born in the state of New York (exclusive of New York City) in 1936. The rate for first births was 32.1 per thousand births; for second births it was 26. It rose gradually for the third and fourth births, and sharply beginning with the fifth births. More than half of the neonatal deaths (54 per cent) were found to occur among infants who were born prematurely, while less

than 3 per cent of the infants surviving the first month of life were premature. The frequency of prematurity was 42.9 per thousand live births. The mortality of premature births was extremely high (389.2), and it rose with the order of birth. The neonatal mortality of infants carried to full term was only 15.2 per thousand live births. The neonatal mortality for male infants was considerably higher than for female infants for every order of birth. Premature births were more frequent in urban communities than in the rural part of the state. However, the mortality among the premature was higher in the rural areas than in the cities. The neonatal mortality of infants born to young mothers and to older mothers is considerably higher than that of infants born to mothers aged from 20 to 30. The lowest rate was recorded for mothers aged from 27 to 28. The same trend of mortality by the age of the mother was observed in practically every order of birth. It started high for young mothers of every birth order, dropped gradually to a minimum and then rose to high rates for old mothers. Neonatal mortality seems to be independently correlated with the order of birth and the age of the mother. Neonatal mortality was found to be closely associated with the age of the father. This association was not due only to the high correlation that exists between the age of the father and age of the mother for, when the age of the mother was held constant, the variation of neonatal mortality with the age of the father was definite. It started high for young fathers, dropped to a minimum, and rose thereafter with the age of the father. The optimal age group of fathers was from 25 to 29.

Production of Ovulation.—In order to determine whether ovulation in the human being could be produced, Davis and Koff administered the gonadotropic fraction obtained from the urine of pregnant mares to thirty-six women who were to be subjected to laparotomy for a variety of pathologic conditions. Many of the subjects were at the period in life in which there is a rapid decrease of ovarian activity. Others had pathologic conditions which would mask any results which might be obtained. The lapse of time between the administration of the substance and the inspection and removal of the ovaries varied. The duration of time that elapsed from the administration of the substance until ovulation was produced was unusually short. It is probable that in many of the experiments maturing follicles

were already present, so that completion of the process resulting in ovulation was rapid. On the other hand, in the women who were in the latter half of the cycle, maturing follicles ordinarily should not have been present and yet rapid ovulations took place. The authors are of the opinion that this substance is capable of causing rapid growth of the follicle and that these follicles rupture, release their ova and are converted into corpora lutea all within the space of from twenty-four to thirty-six hours. The majority of recent ovulations were found in women between the fifth and the thirteenth day, and between the seventeenth and the twenty-fifth day of their cycles. In some of these women it was impossible to date the cycle. In three women who had metrorrhagia and no definite menstrual rhythm, ovulations were present in all. This fact is of importance in that it may point the way to a clinical use for this substance. However, ovulation did not occur in three women in whom the endometrium showed typical glandular hyperplasia. Clinically, this gonadotropic hormone should prove efficacious in the therapy of patients in whom follicular growth and ovulation are at fault.

Streptococcus in Trichomonas Vaginitis.—Hibbert and Falls list three possible explanations of the clinical observations made so far by investigators studying *Trichomonas vaginalis* vaginitis: (1) an independent causative agent other than the trichomonad, (2) the symbiotic relationship between the trichomonad and the streptococcus as the causative factor and (3) the possibility that the failure of patients harboring the parasite to exhibit clinical manifestations of vaginitis may be due to individual immunity established for one or both of these organisms. The authors deal chiefly with the first of these possibilities. The established pathogenicity of *Streptococcus subacidus* was proved in their work by experimental inoculation of five patients with a pure culture of the organism. Definite pathologic changes were produced in the vagina in four, while in the fifth patient vaginitis was not observed. Objectively the symptoms produced were intense redness of the cervix, vaginal mucosa and vulva, and a gray-white, sticky discharge. Subjectively the patients all complained of a tenderness, burning and itching about the vaginal orifice and a whitish discharge. The symptoms were allowed to remain untreated for from three to four weeks. The treatment instituted was as follows: At no time was any bactericidal agent applied to the vagina; the vaginal tract was first cleansed of accumulated debris with cotton. Then a sterile cotton tampon saturated with a broth filtrate of *Streptococcus subacidus* was packed against the cervix and allowed to remain in place for twenty-four hours before removal by the patient. An intradermal injection of a standardized vaccine made from *Streptococcus subacidus* was also given at this time. The interval between treatments was one week, and the treatments were discontinued during menstruation. All four of these patients were successfully treated and rendered symptom free in from four to seven treatments. The patients have been absolutely free of symptoms for from three to six months. The authors were able to fulfil Koch's postulates: (1) the successful inoculation of a normal patient with a pure strain of a known organism, (2) the reproduction of the characteristic pathologic condition in the host, (3) the recovery and reidentification of the organism from the lesion produced, (4) the successful treatment of the patient by the use of a vaccine made from that organism and the local use of the broth filtrate and (5) the definite demonstration that a specific antibody was produced against the organism introduced. Further efforts to eradicate this streptococcus from the genital tract and to raise the general immunity to this organism seem the logical way to attempt the control of this infestation.

Comparison of Young and Old Primiparas.—Galloway and Paul discuss two groups of primiparas (288 more than 35 and 300 less than 25 years of age) delivered by the same physicians in a private hospital. They find that the average length of labor is increased in the older primiparas but that the duration of labor is of little importance. Toxemia increases with age. The incidence of cesarean section increases likewise probably because of fear and because more of the risk is put on the mother and less on the baby, in order to assure a living child and what, in many cases, will be that family's only off-

spring. It increases also because malpresentations and toxemia increase. The incidence of prematurity increases with age and this factor alone might account for the increase in fetal mortality; because when the gross fetal mortality is broken down into unavoidable and obstetric the increase is found in the unavoidable group. Malpresentations increase, and in turn the added number of these leads to an increase in operative delivery. Why there should be more posterior cephalics, more breech presentations and other odd positions of the fetus among older primiparas it is not possible to state. There were no maternal deaths among the 300 primiparas less than 25 years of age, but three deaths occurred in the primiparas of 35 years or more. All three of the mothers who died were delivered by cesarean section. There were nineteen women among the elderly primiparas in whom the presence of fibroids was a complicating factor, whereas among the 300 young primiparas there were no such cases. Among these nineteen cases there were eleven cesarean sections. Myomectomy at the time of cesarean section is inadvisable, owing to the profuse hemorrhage that generally occurs. Subsequent myomectomy is safer. Only twenty-five of the fifty-one patients delivering for the first time at the age of 40 or more could be traced. Twenty of these stated that both mother and offspring were well. One mother said that her baby, now 13 years of age, had been an invalid since birth by cesarean section; the nature of the invalidism was not stated. One mother refused to give any particulars about her welfare or that of her baby. Cancer developed in three mothers, and two of these had already died.

Test for Diagnosis of Venereal Bubo.—Greenblatt and Sanderson produced experimentally a typical textbook picture of chancroid disease in all its phases in a human being by the injection of Ducrey bacilli into the preputial fold. The organism used for this experiment was isolated in pure culture from a chancroidal bubo and maintained in the laboratory for ten months. Two additional observations which should serve to dispel the widespread doubts as to a specific causal organism in what is clinically known as soft sore or chancroid are (1) the reisolation in pure culture, by separation, of the Ducrey bacillus from the secondary lesions and (2) the fact that pus aspirated from the experimental bubo had specific antigenic qualities in that positive cutaneous tests were evoked in known cases of chancroid infection. *Haemophilus ducreyi* can be cultivated with moderate success by growing it beneath the surface of whole defibrinated human blood. The bacillary antigen prepared from such cultures is preferable to bubo pus antigen for a diagnostic cutaneous test. The former gives consistently stronger and more clearcut reactions than the latter. The antigenic quality of chancroid bubo pus is variable, while that of bacillary antigen is constant. The chancroid bacillary antigen as prepared by the authors gave reactions identical to those of dmelcos vaccine. The intradermal chancroid bacillary antigen test is an aid in the

differential diagnosis of genital lesions. The buboes of syphilis, gonorrhea, chancroid and venereal lymphogranuloma as well as the pseudobubo of venereal granuloma frequently simulate one another. A positive intradermal chancroid test commits one to the diagnosis only when the Frei tests, Wassermann reactions, biopsies or smears for venereal granuloma and the like are negative. A repeatedly negative test is of diagnostic value in that it rules out chancroid disease. The various venereal diseases may occur simultaneously in any combination or permutation. A positive chancroid cutaneous test, therefore, in the presence of a positive Frei test, is only presumptive evidence and can be interpreted as diagnostic only when supported by other laboratory evidence such as the cultivation of the Ducey bacillus.

Erysipelas.—Toomey studied the records of the patients having erysipelas who died at the Cleveland City Hospital from 1925 to 1937. It was found that those who died were (1) infants less than 1 year of age, especially those with vulval or abdominal erysipelas, (2) patients more than 50 years of age, (3) patients with pulmonary disease such as tuberculosis, bronchopneumonia and lobar pneumonia, (4) patients with chronic organic disease such as chronic myocarditis, valvulitis or arteriosclerotic disease, (5) patients with concomitant acute infections such as influenza and other infectious or contagious diseases, (6) patients who had a severe debilitating illness immediately before the attack of erysipelas, (7) patients with acute or chronic alcoholism and (8) patients who had suffered some injury. Not all patients in these groups died, but all of the patients who died belonged to one of these groups. Only two patients died simply from erysipelas. They were both obese women with questionable pulmonary involvement. Those who were not in these categories recovered, regardless of how many attacks of erysipelas they had had, how often the lesions had spread or what kind of therapy was used. The value of any remedy for erysipelas should be gaged by its ability to save the patients who fall in those groups who usually die; the other patients get better anyway. The benefits that result from the use of newly discovered therapies are sometimes so obvious that control cases seem unnecessary. This is not true of erysipelas antitoxin, but with sulfanilamide in the treatment of erysipelas it is true. With antitoxin the results were questionable save in infants. Seventy-two of seventy-six patients treated with sulfanilamide have recovered and three have died, a mortality rate of 4 per cent. With the use of sulfanilamide the lesions of erysipelas become dusky red and purplish within

the first twelve to twenty-four hours and disappear completely within four to ten days. The inflammatory reaction is likewise gone and the patient is subjectively better within twelve to twenty-four hours. No patient has had massive local desquamation following this treatment. The temperature comes down in a few days and usually by lysis. The lesion spread in only two cases. The author concludes that, if the experience at the Cleveland City Hospital is the general experience, sulfanilamide will become the drug of choice in the treatment of erysipelas. In cases of hepatitis or sensitivity to sulfanilamide, antitoxin should be tried. An effort should be made to institute treatment early.

Treatment of Undulant Fever.—Flippin used a sterile polyvalent antimelittensis serum of bovine origin with preservative in the treatment of five proved cases of undulant fever. Two separate groups of cattle were used in the production of the antiserum. One group received, intravenously, ascending doses of heat killed suspensions of *Brucella abortus*. The other group received heat killed suspensions of *Brucella melitensis*. The series of injections (three per week) necessary to produce an agglutinin titer of 1:1,600 or more against the specific antigen required approximately two months of such treatment. Serums of individual bleedings from each group having sufficient potency, to which 0.35 per cent phenol had been added as a preservative, were pooled and allowed to age. Equal parts of *Brucella abortus* antisera and *Brucella melitensis* antisera were mixed and filtered. The final mixture had an agglutinin titer of 1:800 against both *Brucella abortus* and *Brucella melitensis*. The treatment varied at first, but now the author believes the method of choice is an initial intramuscular injection of 1 cc. of serum as a test dose followed in twenty-four hours, if no reaction occurs, by six daily intravenous injections of 50 cc. of serum. The serum is best given with 100 cc. of physiologic solution of sodium chloride over a period of fifteen minutes. The duration of the patient's illness varied from one to thirteen months. At the present time all five patients are in good health, with apparent cures ranging in duration from eight to twenty-four months.

Hyperparathyroidism.—Garlock suggests that the surgeon, when confronted with suspicious osseous lesions evident in the roentgenograms and serum estimations of calcium and phosphorus which are outside the normal limits and in spite of the fact that calcium metabolic studies may show a negative balance, should not be too hasty to advise exploration of the neck for a parathyroid adenoma. When doubt exists as to the diagnosis, additional investigation should be undertaken to clarify the situation. This consists of x-ray examination of the skeleton to determine whether the osseous lesions have a predominantly unilateral distribution and the biopsy of the bone in question. The latter will definitely establish the diagnosis by differentiating the characteristic histologic pictures of polyostotic fibrous dysplasia and hyperparathyroidism.

Dihydrotachysterol in Postoperative Tetany.—Pickhardt and Bernhard report their experience with a 0.5 per cent sesame oil solution of dihydrotachysterol in the treatment of five cases of tetany following surgery on the thyroid. The conclusion is that dihydrotachysterol has great value in the control of postoperative tetany. The symptoms of tetany can be alleviated within forty-eight to seventy-two hours after treatment has been instituted. Therapy with dihydrotachysterol must be strictly individualized, i. e. the blood calcium level must be carefully checked at intervals before and after

medication has been instituted. Until the maintenance dosage has been determined, the amount of dihydrotachysterol given by mouth may vary from 1 to 3 cc. every other day to 1 to 2 cc. weekly, depending on the severity of the deficiency. The authors have on occasion administered dosages as high as 10 cc. daily for a period of several days, but during this period the patient's serum calcium was checked carefully. The product is not harmless, and excessive dosage may well induce symptoms of hypercalcemia. A plea is made for the routine determination of serum calcium both preoperatively and postoperatively in all thyroidectomies. The authors found this new substance of definite value from both a subjective and an objective standpoint in the control of tetany. These observations, taken in conjunction with those of Holtz and his co-workers, would suggest that dihydrotachysterol merits further chemical study and it is recommended for the treatment of postoperative hypoparathyroid tetany.

Lipoid Nephrosis.—Murphy and his co-workers report their nine cases of lipoid nephrosis in order to (1) show by histologic and prolonged clinical study that lipoid nephrosis is different from chronic glomerulonephritis with the nephrotic syndrome and that there is justification on clinical grounds alone for this distinction, (2) establish lipoid nephrosis as a clinical and pathologic entity, (3) show that patients with lipoid nephrosis recover while those with chronic glomerulonephritis usually do not and (4) present a clinical study with prolonged observations and histologic examinations which may help to clarify some aspects of the controversy and may help to establish the individuality of lipoid nephrosis. Two patients died and were studied after death, six recovered completely and one is still under observation. The period of study of these patients varied from three months to fifteen years. Most patients were observed longer than seven years. The histologic examination of the kidneys of the two patients who died failed to show evidences of chronic glomerulonephritis. Degenerative changes characteristically described as features of lipoid nephrosis were present. In one case the special staining methods of Bell were used, and not even thickening of the basement membrane of the capillaries was observed. A satisfactory explanation is lacking for the hyperpermeability of the capillaries of the glomeruli. The present report tends to support the view that there is justification for the distinction between lipoid nephrosis and chronic glomerulonephritis. The authors believe that there are ample grounds for this because of the favorable prognosis in lipoid nephrosis as contrasted with the poor one in chronic nephritis. Although lipoid nephrosis is a rare disease compared with chronic nephritis, there is sufficient reason for maintaining the distinction of lipoid nephrosis in the classification of Bright's disease.

Pneumococcic Endocarditis.—During a period of twenty-three months 655 patients were admitted to the medical service of the Cincinnati General Hospital with acute pneumococcic infection, in nineteen of whom the diagnosis of acute endo-

carditis was made, either clinically or by pathologic and bacteriologic methods, giving an incidence of 2.9 per cent. Seventeen of the patients were observed by Rueggesser. In the literature the incidence has been reported as varying from 0.06 to 2 per cent. Whenever clinical and necropsy incidences are recorded the impression is that pneumococcic endocarditis is considerably more common than is usually supposed. A consideration of the relative frequency of the etiologic agents of bacterial endocarditis tends also to show that the importance of the pneumococcus may have been underestimated. During the same twenty-three months forty-six necropsies revealed acute or subacute vegetations on one or more valves, and in fifteen cases the vegetations were proved to be due to the pneumococcus. Preexisting disease of the valvular endocardium apparently has little influence as a predetermining factor in pneumococcic endocarditis. In the nineteen patients, valvular incompetence due to an antecedent infection was diagnosed only once, although two other patients had a history of rheumatic symptoms. Four of the patients had serologic evidence of syphilis, but none had signs of syphilitic aortitis or valvulitis. The endocarditis followed frank lobar pneumonia in fifteen patients while under observation, or there was a history typical of that disease. Pneumococcic endocarditis usually occurs as a complication or sequela of pneumococcic pneumonia, runs an acute course, attacks especially the valves of the left side of the heart, is characterized by embolic phenomena and terminates in the majority of instances in purulent meningitis. As serum and chemotherapy of pneumococcic endocarditis has been almost uniformly unsuccessful, therapy should be largely prophylactic; the prevention of bacteremia by means of potent specific serum and the removal or drainage of purulent foci.

Esophageal Hiatus Hernia.—Diaphragmatic hernia and the esophageal hiatus type in particular offers an example of a disease the study and elaboration of which is dependent on the use of the x-rays. Eisen divides these hernias into three anatomic types: short esophagus, para-esophageal and gastro-esophageal types. The condition is now regarded as comparatively common. Examination of several large series of published cases reveals a preponderance of females, the ratio to males being about 2:1. In the authors' thirty-three cases there were twenty-two females. Since abdominal distention plays an undoubted part in the etiology of this condition, this

predominant female incidence might be explained by multiple pregnancies and the greater tendency to constipation and adiposity in the female. When the bodily habitus is mentioned, it appears that the condition is more common in the stocky or sthenic types. The average age of the patients was 53 years, the youngest 25 and the oldest 78. The thirty-three cases were encountered in the course of a routine gastrointestinal x-ray examination of 1,138 patients. The size of the hernia varied from that of a cherry to that of an orange. The condition may be incidental and symptomless, or it may simulate a chronic cholecystitis or a peptic ulcer. Less commonly there may be dysphagia or anginoid symptoms. All symptoms are worse after a heavy meal and on lying down and are relieved on standing or vomiting. There are no characteristic physical signs. Roentgenologically, a characteristic protrusion of the fundus of the stomach is seen above the diaphragm. Roentgenologically the condition must be differentiated from ampullary dilatation of the lower end of the esophagus, cardiospasm, ulcer of the esophagus and peptic esophagitis, cardio-esophageal relaxation, cancer and diverticulum of the lower end of the esophagus, a diverticulum of the stomach and hour-glass stomach. Medical treatment is largely symptomatic and usually satisfactory. Surgery is indicated in cases in which the symptoms are severe and do not respond to medical treatment. The short esophageal type is not amenable to surgery. Recurrences are not uncommon.

Experimental Drowning.—Banting and his co-workers discuss some of the physiologic mechanisms that they observed in experimental drowning. The condition is essentially one of asphyxia. There are two types of drowning. In type 1 there is a period of apnea during which time there occurs an initial struggle followed by a cessation of movement and then swallowing takes place. When the stomach is distended a period of spasmodic convulsions intervenes, followed by vomiting. This period of apnea is replaced by an interval during which from two to ten gasps occur. Reflexes then disappear and somatic activity apparently ceases. In type 2 drowning the sequence of events in the apneic stage is practically the same as in type 1 but is not followed by gasping. Consequently little if any water enters the lung and death is due to obstructive asphyxia. The cardiac rate and blood pressure present terminally distinctive differences in the two types. In type 1 the pressure falls suddenly just before death to approximately zero; the cardiac rate likewise decreases suddenly, fibrillation frequently occurs and electrocardiographic activity ceases within one to two minutes. In type 2 the blood pressure falls more gradually, the cardiac rate decreases to from ten to fifteen beats per minute and later the ventricular complexes disappear. The auricular complexes may be present for from thirty to forty-five minutes after death. The necropsy in experimental drowning shows the lungs to be hemorrhagic and edematous. In both types of drowning edematous fluid and froth is found throughout the bronchial tree and exudes freely from the cut surface of the lung. Much more fluid and froth are found in type 1 than in type 2 drowning. A variable amount of water is found in the lungs, depending on the number of gasps. If dyed water is used and the lungs are examined immediately after death, irregularly stained areas, extending out to the periphery of the lung, are seen adjacent to tissue which appears unstained and relatively normal. Microscopically the tissue resembles that found in acute pulmonary edema. Invariably the right side of the heart is found to be greatly distended, the left contracted and empty. From the experimental results obtained the following resuscitation measures are recommended: As soon as a person is recovered from the water he should be held up so that water may drain from the stomach and lungs and then placed in the prone position. All foreign matter should be removed from the mouth and larynx, the tongue pulled forward and the Schafer method of artificial respiration immediately started. If a free passage of air in and out of the chest cannot be detected, the larynx should be swabbed with 10 per cent cocaine or a catheter passed into the trachea. Insufflation of 20 per cent carbon dioxide and 80 per cent oxygen has been found to be most effective, delivered at 3

liters per minute into the trachea. If intubation has not been done this gas mixture may be delivered through a nasal catheter into the pharynx. In type 2 drowning it is suggested that a pearl of amyl nitrite blown in through a tracheal catheter before insufflation is begun is most effective. Epinephrine 40 minims (2.5 cc.) of 1:1,000 has been found to be indicated to assist the cardiac action. Atropine from $\frac{2}{100}$ to $\frac{4}{100}$ grain (0.0013 to 0.0026 Gm.) injected intravenously decreases the froth and edema in the lungs as well as increasing the cardiac rate and removing inhibitory influences of the parasympathetic nervous system. It is highly important to keep the patient warm and to massage the extremities toward the heart.

Atabrine in Control of Malaria.—On Jan. 4, 1937, Holton and Winchester made a survey of 1,848 industrial and agricultural workers and prepared thick blood smears. All blood smears throughout the period were examined by the state health department of Georgia. Every person, regardless of the presence or absence of parasites in the blood, was given 0.3 Gm. of atabrine daily for five days. The atabrine was administered personally by trained public health nurses so that no error could occur from irregularity of treatment. Two weeks later a second survey was made during which 1,102 blood smears were examined. All persons who had had positive blood smears on the first examination were included in the second examination. All persons with positive blood smears at the second examination were given 0.02 Gm. of plasmochin daily for three days. On March 22 a third blood smear was taken of all persons who had had positive results in the blood at the beginning of the experiment. The total parasite index for all ages decreased from 8.5 to 2.9 per cent after the first course of atabrine. The third reexamination of the 157 individuals whose smears were originally positive showed two positives, both in the adult group, one of which had been diagnosed *Plasmodium falciparum* infection previously, but which was probably a mixed infection of *Plasmodium vivax* and *Plasmodium falciparum*. This blood now showed only *Plasmodium vivax* parasites. The second patient had *Plasmodium falciparum* parasites at both examinations. In no case throughout the entire experiment did clinical symptoms of malaria appear after a single course of atabrine or plasmochin. The single five day course of atabrine accomplished a parasitic cure in 90 per cent of *Plasmodium vivax* infections and in 79 per cent of *Plasmodium falciparum* infections. After the additional three day course of plasmochin to the patients not parasitically cured by atabrine, all those infected with *Plasmodium vivax* and 99 per cent of those infected with *Plasmodium falciparum* were free from parasites.

Pneumococci Related to Types XI and XVI.—Finland and Brown studied a number of strains of pneumococci that are immunologically closely related to typical strains of both type XI and XVI pneumococci but that are probably distinct from either of these types. One such strain was previously observed by Wirth and Bander and called "double-type XI-XVI." By tests for agglutination, passive protection in mice, capsular swelling and absorption of agglutinins the strains exhibiting cross agglutinations were shown to be distinct from either type XI or XVI but immunologically related to both.

Prostigmine in Myasthenia Gravis.—Tarlau reports two cases of myasthenia gravis in which the use of prostigmine orally elicited a temporary remission of symptoms in one case, although this patient subsequently died, and a complete remission for nine months (to the time of writing) in the other. In the patient who finally died there developed a rapidly increasing tolerance or refractoriness to the drug. This phenomenon was not observed in the other case and has heretofore not been stressed in the literature. Prostigmine was found to be more effective than any other medication used, but the problem of myasthenia gravis is still unsolved and probably will remain so until the etiology is established.

Serum Treatment of Pneumonia in Childhood.—Nemir compares the results of antipneumococcus serum in 151 cases of pneumonia in infants and children with 253 control cases treated over a period of five years. The evidence shows that types I and XIV serums are valuable and effective therapeutic aids. In a few patients types VII, V and II serums were similarly valuable. Even though a dramatic response to serum therapy may be obtained, other considerations are important prior to the decision to use antipneumococcus serum in children. Since the mortality rate of lobar pneumonia is low in children more than 2 or 3 years old, a specific therapeutic agent is not imperative. Pneumococcus serum involves a minimal sensitization to horse serum. Sensitization has not been demonstrable in several cases as shown by cutaneous and ocular tests at a later time. Two patients were treated a second time, one from three to four weeks later, and the other one a year later without any reaction in the first and an accelerated serum sickness in the second. Treatment of patients with serum late in the disease is probably useless in patients less than 12 years old, since it appears to affect mortality only slightly and complications not at all. However, in the presence of a bacteremia, even though discovered late, serums shown to be effective (in types I and XIV, and probably in VII, V and II) are advised. Bacteremia, a rare complication in children, when present indicates severe and overwhelming infection. Most workers with antipneumococcus serum have constantly emphasized the importance of early treatment. Infants severely ill with type XIV pneumococcus pneumonia should receive homologous serum early in the disease, since in this age group (less than 2 years) the mortality rate is high. The use of a combined nonspecific serum in the treatment of a severely ill infant or child before the pneumococcus is typed is not recommended. Serum is effective only for the specific type associated with the disease. Although the efficacy of serum has been demonstrated previously, the author advises its use only for those severely ill patients whose cases are diagnosed early and for young infants, in whom the mortality rate is high. The mortality rate was low in the two groups that he considers and the administration of serum showed no reduction. The incidence of empyema was reduced in patients with types I, XIV and V lobar pneumonia receiving serum early in the disease. A dramatic precipitation of the crisis was observed in the majority of patients treated with specific antibody within twelve to eighteen hours after the first treatment.

Creeping Eruption.—Creeping eruption is a public health problem. It is probable that many cases are never reported or recognized and that the condition is more widespread than now considered. Interest of the proper authorities should be

aroused in order to prevent the dissemination of this troublesome infestation at beaches. Sandler deals only with creeping eruption as originally described by Kirby-Smith, Dove and White and caused by the larval stage of the nematode *ancylostoma braziliense*. The distribution of the eruption in the United States has been confined principally to the coastal plains from New Jersey to Texas, with most of the cases occurring in Florida. Thoroughly freezing the suspected area with ethyl chloride is often effective, or compresses of cotton saturated with ethyl acetate may prove curative. All dogs and cats (including pets) should be denied the privilege of beaches. Tetrachlorethylene is the standard drug for removing hookworm in veterinary practice.

Anal Fissure.—Speare and Mabrey treated fifty-three patients with anal fissure with oil injection. With the patient in the right Sims position the skin about the anus is prepared as for an operation and 1 per cent procaine hydrochloride is injected subcutaneously through a 26 gage, 4 cm. needle, beginning about 2 cm. from the posterior commissure. This infiltration is carried out fanwise and may be extended into the external sphincter. This injection may be dispensed with, since that of the oil causes only slight discomfort. With the left index finger in the anus as a guide, the solution of oil is injected slowly with a Luer Lok syringe through a 24 or 25 gage needle. Injection is continued as the needle approaches the external sphincter, and the solution is injected into the muscle and under the ulcer. The amount used varies from 1 to 5 cc. The treatment may be repeated at weekly intervals. The authors' patients received from one to four injections. After the injection the patient usually has immediate relief

of pain. Complications must be considered. In two of the patients small abscesses developed at the site of injection one week after treatment. These were opened, with subsequent healing of the fissure. One patient had a pinhead-sized area of cutaneous necrosis. A small superficial fistula developed in another. Two solutions have been used for injection: oil of sweet almonds containing 0.5 per cent nupercaine, 1 per cent phenol and 10 per cent benzyl alcohol and a solution of peach-kernel oil containing 1.5 per cent procaine hydrochloride, 6 per cent butesin and 5 per cent benzyl alcohol. Of the thirty-nine patients treated, 62 per cent were relieved and 38 per cent had recurrences after three months. In comparison, 83 per cent of thirty-five patients were relieved by operation and nine of ten patients gained relief from various kinds of treatment (liquid petrolatum, sitz baths and cauterization with silver nitrate). The main feature in the treatment by the injection of oil is that anesthesia is prolonged with resulting relaxation of the sphincter, pain is relieved and freer drainage is established. Whereas before the injection digital or instrumental examination may be impossible, immediately after the injection it can be performed without pain. The anesthesia lasts from one to three weeks, gradually wearing off. In most cases, especially those patients having simpler fissures without large sentinel piles and underlying pockets, healing takes place before complete sensation returns. The avoidance of a hospital stay, rather than superior results, justifies the use of this method as against operation, which can be performed later if the injections of oil fail.

*Studies on Trichinosis: VII. The Past and Present Status of Trichinosis in the United States and the Indicated Control Measures. M. C. Hall.—p. 1472.

Control Measures in Trichinosis.—According to Hall, the problem of trichinosis in the human being in the United States rests primarily on a basis of swine trichinosis, and swine trichinosis rests primarily on a basis of feeding swine raw or inadequately cooked scraps of pork in garbage, table scraps, swill and the like. The rat plays a minor and not definitely ascertained part in the production of swine trichinosis. The basic solution of the problem is keeping raw and inadequately cooked scraps of pork out of the feed of swine. The control measures invoked in the last fifty years have not visibly lowered the incidence of trichinae in man and swine. The control of trichinosis calls for improvements in methods of raising swine, and these improvements should be specified by the packers as requisites to be met by swine growers before swine can be purchased for marketing as pork and without the need for specific measures to destroy trichinae that may be present in the pork. Packers and swine growers can play a big part in controlling trichinosis, eliminating that hazard to the public health and protecting the swine industry and the packing industry from repercussions that may be expected in the next few years as a result of increased interest in trichinosis. Useless publicity and ill considered legislation are not the correct control measures for trichinosis. The packer and the swine grower should be called in as cooperators in the control of trichinosis. A campaign, coordinated by the United States Public Health Service and the Federal Bureau of Animal

Industry, should be carried out by state, county and city public health and livestock sanitary officers to eliminate the practice of feeding raw and undercooked scraps of pork to swine, and nationwide inspection of meat by professional and trained personnel should be established.

Diagnostic Tests for Brucellosis.—In an effort to determine the value of the various tests for diagnosing undulant fever, Evans and her associates studied six groups of patients (fourteen cases of brucellosis in the past, four of acute brucellosis, twenty-eight of chronic brucellosis, forty-one of possible chronic brucellosis, 321 subjects ill with many other diseases and with no history suggesting brucellosis in the past and twenty-eight healthy subjects). Data on one or another of the specific tests are lacking in only sixty-one cases. No single test (other than the isolation of the *Brucella* organism from the patient) can be relied on to determine *Brucella* infection in any given case. An agglutinin titer of 1:40 was found to be the minimum suggestive of brucellosis. Forty-six per cent of the twenty-eight cases of chronic brucellosis gave a negative agglutination reaction and four of the seven cases from which *Brucella* was cultivated gave a negative agglutination reaction; therefore a negative agglutination reaction cannot be regarded as evidence against infection. On the other hand, a positive agglutination reaction is evidence of infection. An agglutinin titer of 1:40 or higher occurred about eleven times as frequently in chronic brucellosis as in other diseases. The higher the titer, the greater is its significance. A positive cutaneous reaction occurred more than four times as frequently in cases of chronic brucellosis as in other diseases. It may therefore be regarded as suggestive of infection, though it is less reliable than a positive agglutination reaction. The opsonocytaphag reaction was found to be the least reliable of the specific tests, because positive reactions are not uncommon in other diseases. A positive opsonocytaphag reaction occurred about twice as frequently in chronic brucellosis as in other diseases. Positive opsonocytaphag and cutaneous reactions add weight to the evidence given by a positive agglutination reaction. The combination of all three positive reactions occurred about ten times as frequently in chronic brucellosis as in other diseases. However, all three specific tests gave negative results in two cases from which *Brucella* were obtained.

Conization of Cervix.—Miller and Todd comment on the 899 electrosurgical conizations of the cervix performed at the University of Michigan Hospital during the last four years. The patient is hospitalized for three or four days. When the cutting current is properly combined with coagulation, the operation becomes a bloodless procedure and in this respect is in striking contrast to most cervical amputations, particularly the Sturmdorf operation. It takes about six weeks for complete epithelization to occur following conization. Stricture is prevented by placing an iodoform wick in the cervical canal at the time of operation in all patients except those who are to have a subtotal hysterectomy. This wick is removed on the third day and the patient is discharged with instructions to take a daily cleansing douche and report twice a week for check-up examination. At this time the cervix is painted with an antiseptic, and a sterile sound or a hemostat is passed into the canal. This procedure is repeated at intervals of two weeks until epithelization is complete. The authors believe that conization is indicated in (1) the correction of minor cervical disease and the prevention of remote complications of the cervix, in patients for whom subtotal hysterectomy is planned, (2) the eradication of deep seated, chronic infections of the cervical canal in older women, (3) for any condition of the cervix for which the Sturmdorf operation is indicated, (4) for obtaining adequate biopsy material in cases in which original biopsy material presented cytologic abnormalities strongly suggesting neoplastic change and (5) as a substitute for older methods of trachelorhaphy in most women, but especially in elderly women. No serious immediate complication occurred in any of the 899 conizations. During the first few days there is little discharge and no discomfort but on the third or fourth day the discharge becomes profuse and is often bloody. Normally this serosanguineous or bloody discharge persists for two weeks, after which it gradually decreases. Vaginal cleansing douches are essential during this period of healing. Ultimate healing with complete epithelization renders the cervix clean and normal in appearance. In a few patients small areas of delayed epithelization are noted. In these, healing may be hastened by the use of the fine nasal tip cautery. As strictures do occur (6.45 per cent positive and 2.51 per cent probable), some of them severe, warrants care in the selection of patients for conization and careful observation afterward.

Hemoglobin After Blood Transfusion.—Sibley and Lundy found that, in the average case in which 500 cc. of citrated blood was given by transfusion, there was an increase of about 1.5 Gm. per hundred cubic centimeters (about 9 per cent) in the value for hemoglobin of the recipient's blood. This increase occurred at the end of the second day after

transfusion and tended to drop to about 1 Gm. per hundred cubic centimeters (approximately 6 per cent) by the tenth day after transfusion. It appeared that when 500 cc. of citrated blood was given by transfusion an increase in value for hemoglobin of from 2.12 (about 12.72 per cent) to 2.8 Gm. per hundred cubic centimeters (about 16.8 per cent) could be expected in those cases in which reactions to the transfusion did not occur and in which bleeding did not follow transfusion. The amount of the recipient's increase in hemoglobin was directly proportional to the value of his hemoglobin before transfusion. There was definitely less increase (about 50 per cent) in the hemoglobin when a reaction to the transfusion occurred than when a reaction did not occur.

*Prophylactic Use of Scarlet Fever Convalescent Serum: Analysis of Results in 1,061 Cases. M. Hardgrove, Milwaukee.—p. 821.

Prophylactic Scarlet Fever Serum.—Hardgrove states that of 1,179 questionnaires sent out to physicians using scarlet fever convalescent serum 1,061 gave information as to the age of the exposed individual, the number of days of exposure before receiving serum, the amount of serum used, the intimacy of contact, whether the patient was removed from the source of exposure, whether Dick tests had been performed and whether reactions occurred which could have been caused by the serum. Scarlet fever developed in the fourteen day period following the injection of convalescent scarlet fever serum in only twenty of the 1,061 cases. In twenty-two other cases a disease developed which may have been scarlet fever without rash (atypical scarlet fever). If this group of atypical scarlet fever cases, excluding two which occurred after fourteen days, is added to the group of fourteen-day true failures, it may be said that the serum failed to protect 3.77 per cent of the 1,061 individuals exposed. There were twelve cases in which early symptoms of scarlet fever were present at the time the serum was injected. In all these twelve cases the symptoms were relieved and no rash appeared. All of those in whom the disease developed within fourteen days were in the group of known intimate exposures. Reactions were observed in 1 per cent of the cases following the use of convalescent serum. These reactions consisted of slight transient elevations in temperature, occasional urticaria and joint pains lasting but a few days. When it is necessary for a susceptible contact to remain in the presence of a person with scarlet fever, convalescent serum should be given at intervals of ten days.

Uremic Intoxication and Pyloric Stenosis.—Falconer and Lyall believe that the usual routine treatment by frequent feedings of liquid food, cessation of alkalis and daily gastric lavage is not sufficient to correct uremic intoxication consequent to pyloric stenosis and that in many patients the administration of saline solution, either rectally or parenterally, is also required. Occasionally refractory cases of persistent vomiting are encountered and feeding by jejunostomy is indicated. Eight cases of pyloric stenosis with vomiting are presented, illustrating the effects of treatment by various preoperative methods. The first two patients died, one as the result of the persistence of vomiting and the other because a major operation was undertaken before the condition had been relieved. The third patient was treated by diet and gastric lavage and responded rapidly to the intravenous administration of hypertonic saline solution. Subsequently gastro-enterostomy was carried out and convalescence was short and uneventful. The fourth patient responded rapidly to simple methods of treatment of uremic intoxication following pyloric stenosis with vomiting. A few days later at laparotomy the diagnosis of cicatricial pyloric stenosis from duodenal ulceration was verified. Gastro-enterostomy was carried out and was followed by a short and uneventful convalescence. Death from pulmonary embolism occurred in the fifth case six days after gastro-enterostomy, which was performed after apparent improvement following saline solution subcutaneously and gastric lavage. At necropsy the kidneys showed macroscopic and microscopic evidence of a nephritis of mixed glomerular and interstitial types. This observation is of importance when correlated with the comparatively poor excretion of urea in the urine recorded throughout the period of observation. The sixth case is one of carcinomatous stenosis of the pylorus with vomiting. The marked improvement, after saline solution and acacia-dextrose solutions intravenously in the biochemical studies, was not accompanied by a corresponding degree of clinical improvement. Subsequent laparotomy disclosed a large carcinoma of the pyloric antrum of the stomach. Posterior gastrojejunostomy was carried out. Treatment by subcutaneous administrations of saline solution was unavailing; death occurred on the fifth day. The cause of death was not ascertained, as postmortem examination was not made. The remaining two patients who recovered show how uremic intoxication due to persistent vomiting from pyloric stenosis responds to feeding by jejunostomy. Routine methods were tried over a period of six days without apparent clinical benefit, but jejunal feedings were followed by a rapid and almost immediate improvement in both the clinical condition of the patient and the constituents of the blood. The levels of the plasma chloride were raised almost to the normal level by saline solutions intravenously, but little or no alteration was effected in the levels of the blood urea, which the authors believe give a better indication of the severity of the intoxication. Jejunal feeding should be maintained until the chemistry of the blood has returned to normal and the daily output of urine is adequate (from 1,000 to 1,500 cc.). When this stage is reached it is safe to undertake gastro-enterostomy, but as long as the tube remains in position there is no need for haste. For this second operation the abdomen may be opened by a left paramedian incision.

Treatment of Undulant Fever with Neoprontosil.—Neumann believes that, if the claims that he puts forward in the treatment of twenty cases of undulant fever are confirmed, neoprontosil and its congeners would be ideal remedies for the disease. Neoprontosil was administered intramuscularly to four patients, the dosage being one injection of 5 cc. on alternate days. The results were disappointing in three cases. During the first week of the fourth patient's (a boy 6 years of age) illness the temperature was as high as 104 F. and the reaction of the blood serum was strongly positive to *Brucella melitensis*, at which time he was treated with intramuscular injections of neoprontosil on alternate days; at the third injection the temperature was 100 F. in the evening and he was completely afebrile on the tenth day of treatment. No second wave of pyrexia occurred, although the patient was kept under observation for six months. In the light of further experience with neoprontosil by mouth it is probable that the dosage administered intramuscularly was too small. Sixteen patients were treated with neoprontosil orally; they were mostly children and the results were gratifying. The initial dosage for children was four tablets of neoprontosil daily. Youths and adults received six tablets. After three or four days, according to the gravity of the case and its response to treatment, the number of tablets was reduced to three in the case of children and to four or five tablets in adults. Usually at the end of a week children were given two tablets and adults three tablets daily, and this was continued for a few days. It is advisable to give the drug for several days after the patient has become afebrile. The effect of the drug on the temperature is usually prompt, and a daily fall of 1 degree F. may be expected. In fifteen of the sixteen cases the average duration of the fever was seven days, ranging from two to twelve days, and in one the drug was apparently ineffective. If no result is evident within a week, the drug will be ineffective even after prolonged administration. If it is given early in the course of the disease, the patient can often return to school or to work within two or three weeks after treatment has been started. No severe toxic effects were observed after the oral administration of neoprontosil. In three cases slight vomiting occurred during the treatment and in one case strangury; both these symptoms disappeared in a day or two when the dose was diminished. In two cases a slight degree of cyanosis of the cheeks was seen. In the two cases in which treatment was not continued for a few days after they became

afebrile the pyrexia reappeared, but it vanished promptly when neoprontosil was again given. Most of the patients were treated in the acute stage of the disease, and more experience in the chronic cases of undulant fever would be desirable.

Raynaud's Disease and Preganglionic Sympathectomy.—Lewis examined six unselected patients with "Raynaud's disease" shortly after preganglionic sympathectomy. Discoloration of the fingers occurred spontaneously or was induced within a few days of operation in three. In one of these three cases the fingers presented nutritional changes; in another there was no trace of such changes. In only two of the remaining three cases could attacks be induced before operation (and in one of these with difficulty); in these two abnormality in the reaction of the fingers to cold could be shown after operation. Preganglionic sympathectomy does not bring the fingers of these patients to a common state; it does give relief, but a local abnormality remains, and this can be displayed in a measure that is related to the abnormality displayed before operation. The attacks in "Raynaud's disease" are not due primarily, as Raynaud thought, to excessive action of the vasomotor nervous apparatus. They are due primarily to a local fault; this may consist of occlusive structural disease or it may not. In the latter instance the digital vessels appear to present increased susceptibility to cold, the reason for which still remains obscure. The full vasodilatation resulting from preganglionic sympathectomy declines during a period of about a week following operation.

Vitamin A Concentrate in Phrynoderma.—Radhakrishna Rao presents two representative cases of papulofollicular dermatosis (phrynoderma) commonly seen in malnourished individuals. While it is generally agreed that phrynoderma is a separate clinical entity associated with malnutritional states, the exact cause of the condition is still not quite clear. Treatment consisted in giving from 10,000 to 18,000 international

units of a vitamin A concentrate daily. Each cubic centimeter of this concentrate, which contains no added vitamin D, contains 72,000 international units of vitamin A. No alteration was made in the diet and no local medication was applied. The results of treatment over a period ranging from fifty to 140 days were satisfactory, but they were not definitely conclusive, as the controls also showed slight improvement during the period of observation.

Prophylaxis of Constriction Ring Dystocia.—Phillips believes that the localized contraction of the uterus, *constriction ring*, is always preceded by a longer or shorter period of that painful and ineffective activity of the uterus, well described by the old clinical term *colicky action* of the uterus. *Colicky action* of the uterus can be recognized by the simple clinical observation that the painfulness of the uterine contraction persists after the palpable hardening brought about by uterine contraction has passed off. Prompt recognition and unremitting treatment of this *colicky action* until it has ceased will prevent the onset of a constriction ring and so do away with one of the most vexatious and dangerous complications of labor. The author's practice now is, when these troublesome *colicky pains* are suspected, immediately to place his hand on the uterus and to get the patient to describe the exact duration of the pain she is experiencing. Should it extend to or beyond the cessation of the uterine contraction, one can be certain that *colicky action* has started. It must be controlled at once by an efficient antispasmodic drug. Preparations of opium are probably the best. The patient must be watched as the influence of the drug ceases. With his hand again on the uterus, the duration of the pain is estimated. The drug must be repeated in this way until the *colicky action* of the uterus has ceased. The pain is always referred to the lower part of the abdomen, just above the pelvic brim, often on one side only. It may begin at or soon after the onset of labor or not until after several or even many hours of feeble infrequent contractions. It may be severe or even excruciating. These are variable features, but invariably the pain will be found to persist after a contraction has passed off. The *colicky action* always begins in and is usually confined to the first stage of labor, whereas the constriction itself, which may follow, usually occurs in or is at least first recognized in the second stage. With each severe pain the woman often struggles and strains. Observing her behavior, the attendant is led to think that she is really in the second stage of labor and she may be urged and encouraged to bear down—a useless effort which may well aggravate the spasm. Puzzled at the delay in delivery, in spite of all these pains and efforts, the attendant is liable to make frequent vaginal examinations, again a procedure which will intensify the spasm. Even abdominal

palpation is liable to irritate such a uterus. But worst of all is the modern blunder—in ignorance of the real state of things—of giving the injection of pituitary extract, which is so effective in properly selected cases of real second-stage delay due to feeble uterine action.

Sulfanilamide in Gonorrhea.—Cokkinis and McElligott discuss the final results of 491 consecutive male and 142 female cases of gonorrhea. They find that the best results with sulfanilamide treatment in gonorrhea can be obtained only by a specialized technic of administration and that incorrect or haphazard chemotherapy is followed by a high proportion of failures. With this optimal technic a permanent cure can be expected in 80 per cent of male patients with one course of treatments extending over three weeks, although all manifestations of the disease usually clear up well within the first week. With additional courses in cases that are resistant or in relapse, the total permanent cures in male patients can be increased to more than 90 per cent. Under optimal conditions the disease in women appears to react equally well to the drug, but these conditions are more difficult to attain because women are more sensitive to its minor toxic effects. A degree of immunity appears to be essential to the attainment of optimal results with sulfanilamide-chemotherapy. Hence the importance of "timing" the chemotherapy correctly and combining it with vaccine treatment. 1. To males with acute infections attending in the first week of symptoms, vaccine treatment is started at once and continued twice a week (starting with 5 and increasing to 100 million) through the chemotherapy. Daily irrigations are given. Sulfanilamide is started from eight to ten days after a discharge has commenced and continued for a full three weeks. The daily dose varies with weight, the usual dose being 4 Gm. daily (0.5 Gm. in a glass of water after the four daily meals). This is continued for the first two weeks, after which it may be diminished to 3 Gm. daily. An alkaline mixture may be given if desired and the patient is seen at least twice a week. A list of instructions is issued, pointing out the importance of strict obedience and absolute continuity of treatment and containing usual directions about avoiding eggs, onions and saline purges as well as prolonged exposure to sunlight. After three weeks

all treatment is suspended and the patient attends weekly for prostatic bead tests, urethroscopy being done on one of these visits. If these are satisfactory, provocative tests are started from three to four weeks later. After passing all tests the patient is kept under observation for a further six to eight weeks, when at least one more provocative test is given before final discharge. If the first course fails or relapse occurs an interval of at least two weeks must elapse before the next course is started. During this interval and after it a mixed gonococcus vaccine is given, while prostatic massage and diathermy are added in cases in which the prostate is enlarged. Patients who fail to react after ten days should be given up as failures for that course, and a further course administered in three weeks. 2. After the first week of symptoms in acute cases the technic is the same, except that sulfanilamide is started at once. Complicated infections can be expected to respond as rapidly as uncomplicated ones. 3. The dosage in patients with chronic infections need not exceed 3 Gm. daily and the total period may be cut down to about seventeen days, while a mixed gonococcus vaccine may be used with advantage. 1. In recent infections in women, vaccine treatment is started at once and continued biweekly as in men. Daily treatment consists only of urethral and vaginal irrigations. In the presence of dysuria an alkaline sedative is given. Sulfanilamide is never commenced before the eighth day of symptoms and is administered continuously for three weeks. An adequate daily dose is 3 Gm. At the end of three weeks, if all tests and examinations are negative, treatment is suspended. The patient is examined fortnightly for one month and then after each menstrual period for a further two months, when a provocative injection of vaccine (500 million gonococci) is given. If tests made two days after this are negative and clinical signs are absent, the patient may be regarded as cured. 2. In women patients who failed to react to the foregoing treatment or in whom the infection relapsed, three weeks should elapse before a further course of sulfanilamide is given. This further course is recommended particularly in cases of proved gonococcal relapse. In the more common relapses due to secondary organisms, the associated vaginitis is treated for two weeks with acetarsone pessaries and daily douches, while a further course of sulfanilamide may be given if no improvement occurs. 3. In women with a chronic infection similar chemotherapy is employed, but acetarsone pessaries are used from the beginning and a mixed gonococcus vaccine is given.

Probable Vector of Endemic Typhus in New Guinea.

—During the last four years Gunther has collected and examined approximately 3,000 larval mites, comprising fourteen species from seventeen hosts. All the species, except certain specimens of *Schöngastia yeomansi*, were collected in the Morobe district of New Guinea. Of all the mites collected, approximately 90 per cent were *Trombicula hirsti*, variety *morobensis*, and of this species nearly all were taken from various common birds. A small number were taken from seven bandicoots and from three men. The only other species taken from man was *Schöngastia yeomansi*, in another district. Since no cases of endemic typhus have been reported from the Aitape district, consideration of *Schöngastia yeomansi* as a possible vector must be shelved. *Trombicula hirsti*, variety *morobensis*, is the most likely suspect. In the Morobe district it constitutes about 90 per cent of all mites taken and is the only species which has so far been found on man. Its presence in such overwhelming numbers is certainly due to its affinity for various common birds. The presence of this species in such large numbers is not incon-

sistent with the possibility of its being the vector, as the majority of those attacking man must come from birds; but a minority must come from bandicoots. Three of the less common species, *Neoschöngastia clauda*, *Neoschöngastia callipygea* and *Walckia buloloensis*, occur on the various rodent hosts, and any one might be the direct vector to man. There is no reason to suppose that they would not attack man; *Schöngastia yeomansi* has been found to do so, proving that this habit is not confined to the genus *Trombicula*. In such a case, however, it is certain that the bandicoot would be infected by either of the first two species, and *Trombicula hirsti*, variety *morobensis*, could also act as a vector. The author regards this last as the probable vector, from bandicoot to man, and the others as the probable vectors between the various rodents. *Neoschöngastia riei* and *Schöngastia rotunda* are apparently only occasional parasites of the bandicoot and appear to be unlikely vectors. The seven remaining species, because they are confined to birds, are quite unlikely to be vectors.

Tuberculosis and Diabetes Mellitus.—Himsworth states that pulmonary tuberculosis was found in fifteen (6.5 per cent) of 230 consecutive cases of diabetes mellitus on their first attendance at the hospital. Two of these patients had tuberculous bronchopneumonia and were readily diagnosed by clinical methods. In the remaining thirteen the diagnosis was made only by x-ray examination. The conclusion is drawn that early pulmonary tuberculosis in the diabetic patient is impossible to diagnose by clinical methods and that a routine roentgenogram of the chest is essential in every diabetic person when he is first seen. The x-ray examination should be repeated every year, or more often if the control of the diabetes is unsatisfactory. The x-ray appearances of the early pulmonary tuberculosis in diabetes are those of a chronic inflammatory lesion, they are identical in appearance with new lesions appearing in the lungs of proved cases of pulmonary tuberculosis and they can progress until they are roentgenologically, and the cases clinically, typical of pulmonary tuberculosis; they are quantitatively correlated with clinical evidence of toxemia. Evidence is brought forward that uncontrolled diabetes predisposes to the development of the pulmonary lesion and conversely that treated diabetic patients are no more liable to develop pulmonary tuberculosis than nondiabetic subjects. When the two diseases are associated, the treatment of the diabetes is of primary importance. The prognosis is excellent if the pulmonary lesion is discovered at an early stage.

Sulfanilamide Derivatives and Spermatogenesis.—Vigoni points out that several months ago Jaubert and Motz reported in the French biologic society that certain sulfanilamide products exert an inhibiting effect on the spermatogenesis. Since this report was circulated widely, the author reviews the observations of Jaubert and Motz and then reports his own investigations on this problem. He studied the spermatogenesis in healthy subjects, in gonorrheal patients treated with the old therapeutic measures, and in gonorrheal patients treated with para-aminophenylsulfamide. The total number was forty-three. In healthy subjects it was observed that the number of spermatozoa varies greatly but that their motility is always good. In gonorrheal patients who were treated with the old methods there were likewise considerable variations in the number of spermatozoa, but on the whole the numbers were inferior to those in healthy subjects; however, it was impossible to establish a relationship between the diminution and the degree of acuteness of the gonorrhea. The motility of the spermatozoa was normal in the chronic cases or in those in which cure was effected but was subnormal in the acute cases. Regarding the spermatogenesis of gonorrheal patients who had received para-aminophenylsulfamide, the author says that, as in the other groups, the number of spermatozoa varied greatly in the different patients. In two cases azoospermia existed. There was no relationship between the quantities of para-aminophenylsulfamide absorbed by the patients and the number of spermatozoa. Some subjects, who had received only a small amount of the medication, had an extremely small number of spermatozoa, while others, who had received rather large doses, had normal or supernormal numbers of spermatozoa. The motility of the spermatozoa, on the other hand, seems to be more often impaired in these patients who were subjected to chemotherapy than in those treated with the old methods. However, this impairment of the motility ceases later on; after an interval of a month had elapsed it had disappeared in all but one of the patients. Of the two patients with azoospermia, only one could be examined later and in this one numerous motile spermatozoa were detected.

Renal Disorders and Deformities of Vertebral Column.—Jasienski calls attention to the fact that renal disorders occasionally are related to deformities of the vertebral column. Congenital scolioses are often associated with congenital malformations of the urinary passages; or the same morbid factor, such as tuberculosis, may cause a deformity of the vertebral column and renal or other urinary disorders. In other cases, one of these disorders causes the other one. The deformity of the vertebral column may be secondary to the primary disorder of the kidney and vice versa. Among the different spinal deformities it is scoliosis which most frequently concurs with renal disorders. An extraordinarily high incidence of chronic appendicitis has been demonstrated in scoliotic children. On the other hand, scoliosis has been observed in the course of renal disorders such as lithiasis, nephritis, paranephric abscess and floating kidney. The author discusses the theories that have been advanced with regard to the pathogenesis of the so-called nephrogenic scolioses and cites his own observations on this problem. He encountered scoliosis quite frequently in renal disorders. In acute renal disturbances it is more the rigidity of the vertebral column than the scoliosis which draws

the attention. In a patient who received surgical treatment for a subphrenic abscess, the author was able to observe the development of a spinal concavity toward the diseased side. He further shows that a deformity of the vertebral column can exert an unfavorable influence on the superior urinary passages. Such a deformity creates unfavorable mechanical conditions for the renal function and the discharge of the urine and thus provokes disorders in the urinary passages. Hydronephrosis, floating kidney, lithiasis and other disorders occur in such patients. Necroses on persons with deformities of the axis of the vertebral column frequently reveal irregularities in the position and shape of the kidney, of the pelvis and of the ureters. The author further states that kyphosis resulting from a tuberculous spondylitis may cause disorders in the urinary tract and he cites authors who observed that Pott's disease is often accompanied by renal lithiasis or by renal tuberculosis. After pointing out that Frangenheim was of the opinion that the lumbar incision should not be employed in patients with considerable scoliosis, he evaluates the different methods that permit nephrectomy in patients with Pott's disease and other deformities of the vertebral column. In the conclusion he points out that, if the impossibility of a lumbar incision becomes evident, two angular anterior incisions should be made: an abdominal one and one along the eleventh rib, which, after liberation of the rib, permits the opening of the tenth intercostal space. He thinks that the incision suggested by Uteau as well as the thoracophrenolaparotomy should be resorted to only in exceptional cases.

Glandular Therapy of Prostatic Hypertrophy.—Following a discussion of the development of the surgical treatment of hypertrophy of the prostate, Cassuto points out that, in view of the fact that the onset of the hypertrophy frequently coincides with a diminished genital function, it has been assumed that the arrested or diminished testicular function is intimately connected with the causation of the hypertrophy. He surveys the literature on the glandular therapy of hypertrophy of the prostate and describes his own experiences with this treatment in thirty-five cases. The results varied. In some the symptoms diminished to the point at which treatment could be discontinued, in others the improvement was only temporary, and in still others there was no effect even after prolonged treatment. In analyzing the effects of glandular therapy on the principal symptoms of hypertrophy of the prostate, the author found that pollakiuria was influenced most effectively; it was favorably influenced in at least twenty-six cases. The anatomic status of the prostate remained nearly always the same, except that in five cases the firmness seemed to be lessened and it even had the appearance of there being a reduction in the hypertrophy. The improvements were obtained in a minimum period of one or two months. If the effect is negative after such a period, the treatment must be changed. The azotemia seems to be improved only in those cases in which there is an appreciable clinical amelioration. In the author's material this occurred in ten of the cases. He employed glandular therapy in addition to surgical treatment in six cases. The postoperative course in these cases was not sufficiently different from the usual course to draw definite conclusions. Testosterone propionate was used.

- *Functional Test of Venous Circulation. D. Olmer, A.-X. Jouve and J. Vague.—p. 1233.
Renal Insufficiency by Habitual Absolute or Relative Oliguria. J. Cottet.—p. 1235.

Functional Test of Venous Circulation.—Olmer and his associates say that the venous circulation is the expression of the combined play of several factors, the most essential of which are insufficiency of the right ventricle, the condition of the large venous trunks and the peripheral venopressure mechanism. The venous pressure, when considered alone, does not permit the definite determination of the functional capacity of the right side of the heart. The authors describe a functional test which they employed systematically for one year in patients likely to present modifications of the venous circulation. In order to explore at the same time the peripheral and the hepatoportal sections of the venous system, they combine the passive raising

of the lower extremities with hepatic compression. The technic is as follows: The patient is in a strictly horizontal position. Then the lower extremities are elevated 60 degrees above the level of the bed; it is essential that the patient remain passive in order to eliminate the play of the muscular contractions; the elevated position is maintained for fifteen seconds. After the inferior members are lowered again, the patient remains in the horizontal position for fifteen seconds. Then hepatic compression is done by pressing the right hand against the anterior surface and the left hand against the flank. The pressure should be moderate so as not to become painful. It is maintained for fifteen seconds. The brachial venous pressure is determined five times: during rest, during the elevation of the inferior members, during the subsequent rest period, during the hepatic compression and after another fifteen seconds of rest. The test requires one minute. The venous pressure is measured by means of the phlebopiezometer of Villaret or by the manometer of Claude. The authors report their experiences with this test on thirty normal subjects and on patients with various pathologic conditions. They found that this functional test of the venous circulation is always positive in cases of insufficiency of the right side of the heart or in total asystole. The evaluation of the results obtained with this test indicates that it permits the determination of the functional capacity of the heart as regards the venous circulation.

Schüller-Christian's Disease.—Esser, after citing the triad of symptoms of the Schüller-Christian syndrome, namely cranial defects, diabetes insipidus and exophthalmos, says that Rowland considered xanthomatous proliferations as the cause and that Ludwig Pick classified the disease with the essential lipoidoses. However, investigations and observations during recent years made it appear doubtful that a disturbance in the lipid metabolism is the cause of the disease, because anatomic studies disclosed that proliferation of reticulo-endothelial elements and granuloma formation precede the depositing of lipoids. The author reports his observations on a child with Schüller-Christian's disease who was under his observation for three years and who is now practically cured. The child came under his observation in April 1935, at the age of 14 months. During the winter the child had had fever and coryza repeatedly, and in the last few weeks the parents had noticed a swelling in the temporal regions. In the course of the examination roentgenoscopy disclosed the cranial changes that are typical for Schüller-Christian's disease. After describing the results of the chemical and morphologic examinations of the blood, the author says that he regards as especially significant the reticulated giant cells, some of which contained cocci, and the foam cells and the debris of foam cells. The sternal punctate disclosed a reduction in the myeloid elements and an increase in the small reticulated cells. Moreover, the author detected in the bone marrow a reticulated giant cell which was filled with cocci to such an extent that it gave the impression of a bacteriologic culture. Under the influence of the customary treatment with a diet that was deficient in fat and free from cholesterol, the general condition became so much worse that the supposed therapeutic diet had to be interrupted and a mixed diet instituted. The cranial defects increased and at the end of three months the child was discharged from the hospital without showing improvement. In the course of the examination roentgenoscopy the author recalled that Letterer, Sherman, van Crefeld and others had observed an infectious reticulo-endotheliosis in which bone defects and cocci were found. On the basis of a discussion of the possible development of this disorder, the author decided to try a diet which was rich in lipoids and fat. In addition to a mixed diet the child was given daily from two to four egg yolks and large amounts of milk. From now on

the cranial changes became fewer and gradually disappeared again. Today the child is well; the cranial defects and changes in the blood have disappeared; only the number of thrombocytes is still increased. At present the author is caring another child with Schüller-Christian's disease. Here the skeletal changes are accompanied by hematic disorder: the reticulated giant cells again have masses of cocci. On the basis of these observations the author concludes that Schüller-Christian's disease is of infectious origin.

Cutaneous Blastomycosis from Wüillemin and Albicans Endomyces with Grave Septicemia: Case. T. Venturi.—p. 450.

Familial Spinulous Keratosis.—Perpignano reports three cases of chronic spinulous keratosis of the neck, thorax and extremities in a man aged 29 and his two children aged 5 and 3 years. None of the patients suffered from endocrine disease or had a history of poisoning from intake of drugs. All were frail, with enlarged laterocervical, axillary and inguinal lymph nodes, and showed signs of chronic bronchitis on auscultation. In all cases the Wassermann and Meinicke turbidity tests for syphilis were negative, the sputum was negative for tubercle bacilli and the skin reaction to tuberculin gave positive results. There was a history of pulmonary tuberculosis in the maternal family. The roentgen examination of the thorax showed slight changes of the lung of the father and the presence of tracheal bronchial adenopathies in one of the children. The author believes that in these cases there was hereditary predisposition to the development of cutaneous diseases which was due to stimulation of the skin by tuberculous toxins. He calls attention to the possible pathogenic role of latent tuberculosis in skin diseases.

Favorable Evolution of Lipoid Nephrosis in Intercurrent Measles. C. Montagna and A. A. Rimoldi.—p. 617.

Immunotransfusion in Children.—Acuña and Fernández resorted to immunotransfusion in sixteen cases of grave infections, especially pneumonia and bronchopneumonia, in infants and children. In all cases the treatments previously given failed. The intervals between transfusions varied from one to two days, the total number of transfusions varied from two to ten, and in rare cases ten, and the total amount of blood for transfusion varied from 20 to 170 cc. Only in rare cases as much as 260 cc. of blood given at one time. The authors stress the advisability of selecting strong, healthy donors without history of syphilis or malaria. Polybacterial vaccines prepared with bacteria killed by heat, or stock vaccine autovaccines prepared from the patient's secretions, were used in immunizing the donors. Several donors were prepared on consecutive days to avoid the constant use of one person. Blood was taken from four to six hours after injection of vaccine. Transfusion was preceded by removal of some of the patient's blood and given slowly by gravity to prevent overcharging of the heart. It was given through the veins, preferably through the longitudinal sinus, in amounts of from 20 cc. of a 0.5 per cent citrated blood for each kilogram of body weight. There were no accidents. One patient of the group of sixteen died. The authors conclude that immunotransfusion is of therapeutic value in infections, especially pneumonia and bronchopneumonia, in infants and children. Earlier administration of the treatment, the better the results. Transfusion must be repeated for good results. It is important to use the proper technic and under the necessary precautions, it is tolerated by infants and children. The selection of donor strains and the type of vaccines used in immunizing the child are determined by the individual case.

- *Technic for Pneumococcic Pleural Empyema in Infants. A. Gomes de Mattos.—p. 185.
Ascorbic Acid in Treatment of Certain Stomatitides. J. F. Barretto.—p. 235.
Complications and Sequels of Grip. M. Schachter.—p. 240.

Pneumococcic Pleural Empyema.—In the treatment of pneumococcic pleural empyema in infants, Gomes de Mattos reports satisfactory results from intrapleural injections of air, followed by lavage of the pleural cavity with a 0.5 per cent solution of ethylhydrocupreine hydrochloride. The puncture is made in the intercostal space over the focus of empyema with a needle of 1.5 mm. caliber which is connected to an aspirating syringe. Aspiration of pus is followed by intrapleural injection of filtered air in the proportion of half the amount of pus removed. The treatment is repeated to obtain complete elimination of pus. In no case is more than 200 cc. of air administered. After removal of pus, the pleural cavity is washed by repeated injection and aspiration of a 0.5 per cent solution of ethylhydrocupreine. When the fluid used in the lavage comes clear, 10 or 20 cc. of the solution is injected, the needle removed and the opening of the puncture covered with either collodium or adhesive plaster. Air is injected only in the first treatment. The subsequent treatments consist only in intrapleural lavage and storage of 10 or 20 cc. of the fluid in the pleural cavity. The best results are obtained when the treatment begins at the end of the third week of evolution of the disease. The average number of treatments is seven, given every other day. However, if the condition of the patient improves the intervals between injections are prolonged or the treatment is discontinued as signs of recovery indicate. In the twenty-four cases reported by the author, the disease was a complication of pneumonia in the majority of cases and of either bronchopneumonia or bronchitis in a few cases. The author concludes that the method of intrapleural injections of air gives a high percentage of recoveries (twenty-two of twenty-four cases) and a low rate of mortality (two of twenty-four cases). It can be resorted to as either a preparatory or a complementary method for a surgical intervention (Cocchi). The average duration is eighteen days. The treatment is indicated in large, small, free and encysted forms of pleurisy in infants. It is of an easy technic, economical and well tolerated by infants.

*Physiology and Pathology of the Thymsus. H. Adler.—p. 614.
Traumatic Luxation of a Chopart Joint. R. Nicole.—p. 650.

Exophthalmic Goiter.—Sunder-Plassmann demonstrated, in dissections on rabbits, that bilateral resection of the cervical sympathetic fibers leaves the finer nervous structures of the thyroid and its vessels largely intact. Microscopic studies of rabbits' thyroid, previously activated by the thyrotropic hormone, demonstrated the manner in which the terminal nervous reticulum comes in contact with the individual follicle cell both on its periphery and with its plasma. He had likewise observed in thyroids activated by thyrotropic hormone a simultaneous enlargement of the follicular cells and an increase in the size of the Schwann's bodies in the preterminal nervous plexus. The terminal reticulum derives from the reticulum of the nonmedullated neurofibrils of the preterminal plexus and constitutes with the latter a single biologic entity. The author further demonstrated that the vegetative nervous apparatus of the gland remained intact as long as the gland was capable of remaining "refractory" to the thyrotropic hormone. As soon, however, as the "refractory stage" was broken, the prethyroid exhibited severe toxic damage particularly in the preterminal plexus and its Schwann's plasmodium. The simultaneous intraperitoneal injection of the thyrotropic hormone and foreign serum (hogs') produced, in a few days, definite toxic damage in the vegetative nervous system. The gland appears to have lost the capacity for resistance, as a result of which the liver interstitium, the liver parenchyma, the adrenals

and the myocardium exhibited severe damage. On the basis of research performed by the author's associates at the Pathologic Institute in the University of Munster, the author rejects the hypothesis of an "antithyrotropic hormone" or of a special "antithyrotropic substance." He assumes the existence of an antigen-antibody reaction due partly to the introduction of a protein so that the smallest amounts of thyroxine in the serum of the previously treated animals may assume significance, and partly to the alterations of the general reaction of the organism in which the vegetative nervous system plays an important part.

Physiology and Pathology of Thymus.—On the basis of a clinically observed case, Adler advances the possibility of causal relationship between hyperplasia of the thymus gland and myasthenia gravis. He demonstrated in dogs that the changes in the muscles in myasthenia are of a chemical nature, that they can be provoked by the hyperfunction of the thymus gland and that the action is to be regarded as the effect of internal secretion of the gland. The striking clinical contrast between myasthenia and myotonia suggests that the latter may likewise stand in causal relationship to the thymus. The frequency of a hyperplastic thymus in exophthalmic goiter suggests that the myasthenic reaction present in a considerable proportion of these cases is due to the hyperfunctioning thymus. The author suggests that the presence of a hyperfunctioning thymus be determined by testing for myasthenic muscle reaction before operating on the thyroid. He advances the theory of a hyperfunctioning thymus as the main cause of postoperative exophthalmic symptoms. It is for this reason that they have adopted in Sauerbruch's clinic the removal of the thymus in addition to strumectomy in the cases of exophthalmic goiter with positive myasthenic reaction.

Acute Myelosis and Agranulocytosis. P. G. Ahlberg and N. G. Norden-son.—p. 258.

Bone Marrow in Typhoid.—Galinowski studied the bone marrow in sixty-three patients with typhoid. The bone marrow was obtained from the sternum by means of Arinkin's method, the puncture being made at the level of the second intercostal space. The bone marrow was examined for the number of erythrocytes, the hemoglobin value, the color index, the percentage of reticulocytes and the number of nucleated elements, with consideration of the proerythroblasts, the erythroblasts and the normoblasts with basochromatic, polychromatic and orthochromatic protoplasm. Simultaneously with the bone marrow, the blood was examined for the number of erythrocytes, leukocytes and thrombocytes, for the hemoglobin content, for the color index and for the percentage of reticulocytes. In summarizing the results of his studies the author says that the number of nucleated erythrocytes per cubic millimeter of bone marrow varied between 1,222 and 33,764. He regards values up to 4,000 as below normal, that is as indication of a reduced erythropoiesis; values between 4,000 and 10,000 as normal, and the values above 10,000 as an indication of an increased erythropoiesis. The author arrived at this classification on the basis of studies on normal persons. Manifestations of increased proliferation of the erythroblastic tissues were observed in the majority of cases during the second and third stages of typhoid. In addition to the duration of the disease, the severity of the course and the complications seem to play a part here. In convalescents and during remissions, the bone marrow usually is in a quiescent state. In the cases in which there was a normal number of erythrocytes in the blood, the activity of the bone marrow was either normal or showed signs of compensatory

activity. In cases in which symptoms of anemia were present, the behavior of the bone marrow was not uniform; in some cases there was no reaction at all, in others there was an erythroblastic hyperfunction and in still others there were signs of exhaustion. The latter were observed chiefly in the more severe degrees of anemia. During the second stage of the severe forms of typhoid and during its third stage in patients with complications, divergences were observed between the reductions of the erythrocyte count in the blood and in the bone marrow. The reticulocyte content of the bone marrow and even more so that of the peripheral blood did not always go parallel to the activity of the erythroblastic system. A simultaneous increase of the reticulocytes in the bone marrow and in the circulating blood was observed in those cases in which the bone marrow was rich in cells and the nucleated erythrocytes showed normal aspects. An isolated reticulocytosis of the bone marrow was frequently observed in connection with a deviation to the left of the nucleated erythrocytes. A stimulation of the erythropoiesis, relative to the leukoblastic system, to an extent that the nucleated erythrocytes amounted to from 25 to 40 per cent of all nucleated elements of the bone marrow, was usually observed during the third stage of the severe and complicated cases.

- Clinical Electrocardiography: Type of Electrocardiogram in Obese Persons. G. Schlomka and H. Blanke.—p. 435.

Sodium/Chloride Index in Hepatic Disorders.—Bansi and Strecker studied the elimination of sodium and chloride and the sodium chloride index of the urine of patients with various hepatic disturbances. The studies were made on forty-two subjects: five normal persons, seven patients with cirrhosis of the liver, eleven with engorged liver, four each with catarrhal jaundice and with obstructive jaundice, three each with malignant tumors of the liver and with acute yellow atrophy of the liver, two with hemolytic jaundice and one each with arsphenamine jaundice, with gumma of the liver and with amyloidosis of the liver. In some of the patients the tests were continued for weeks. With one exception, all the subjects were free from renal disorders. They received a mixed diet, which usually had a low sodium chloride content, and 800 cc. of fluid. The authors say that the elimination of sodium and chloride and the sodium/chloride index are not to be considered as reliable tests for the function of the liver but rather as differential diagnostic and prognostic aids. They think that in diseases of the liver an index between 0.75 and 0.5 indicates a mild impairment, an index between 0.5 and 0.25 a moderate and an index below 0.25 a severe, usually fatal disorder. In cirrhosis of the liver, they observed a great reduction in the elimination of sodium and chloride and a reduction in the index. It was found that the lower the index, the more unfavorable was the prognosis. In carcinoma or in sarcomatous infiltration of the hepatic tissues, the sodium/chloride index as well as the sodium and chloride concentrations decrease as the destruction of the hepatic tissues progresses. In catarrhal jaundice the index decreases to below 0.5 until the height of the disease is reached, but during the period when the jaundice subsides the index rises to above 1 as the result of the elimination of large amounts of sodium. In obstructive jaundice the index values fluctuate considerably, but they remain within normal limits. If the index increases far above 1 in case of subnormal concentration in the urine, this is an indication of acute yellow atrophy of the liver if vomiting exists at the same time. However, an elevation of the index above 1 in the presence of a hypernormal concentration is to be found in the subsiding stage of catarrhal jaundice and during the elimination of edema in patients with heart disease.

Tetanus: Passive and Active Immunization.—On the basis of the review of the literature and their own clinical and laboratory investigations, Rufanov and his associates state that they do not see sufficient reason for rejecting the serum prophylaxis of tetanus. Despite the negative statements of Böhrer, they feel that serum prophylaxis has played an important part in reduction of the incidence of tetanus. The serum, however, should be administered as early as possible, preferably at the time of treatment of the trauma and, because of the rapid disappearance of the passive immunization produced by it, a secondary injection should be given after from seven to ten days, especially in the presence of a soiled wound. Among the shortcomings of passive immunization demonstrated by the authors in animal experiments they mention the short duration of immunity, a diminished effect with each subsequent immunization and the danger of serum disease. To obtain good results with the specific treatment, high doses of the antitetanic serum must be given. The clinical and animal researches of the authors confirm the results of Ramon of the Pasteur Institute as to the effectiveness of anatoxin for the purpose of active immunization against tetanus, its ability to increase rapidly the antitoxic titer after a considerable lapse of time and of complete safety of the method. Simultaneous administration of the serum and of the anatoxin, preferably in oil, constitute, by combining both the passive and the active immunization, the best prophylaxis against tetanus. For purposes of military hygiene the method may be simplified by combining it with vaccination against another infection, for example tetanus and typhus for adults, tetanus and diphtheria for children. The advantages of anatoxin are (1) its ability to lower the incidence of tetanus, (2) lessened danger of anaphylaxis and (3) the reduction of the expenses of serum prophylaxis and of treatment of tetanus.

Purulent Gonitis.—According to Napalkov, the primary and frequently the only method required in the treatment of purulent gonitis is immobilization of the limb, puncture and repeated flushing of the joint. Suppuration of the capsule or of the periarticular tissues requires an incision. Incision of soft tissues about the joint is preferable to initial arthrotomy. The author recommends the use of drains in arthrotomy only when incision is made in the joint capsule but not within the joint. The author limits the indications for resection in purulent gonitis to the initial phase of sepsis. Of the twenty-eight patients treated by the author on the conservative plan, twenty-three were cured and retained the limb. Two patients required amputation and three died.

- Recent Investigations on Coagulation of Blood. T. Astrup.—p. 745.
- *Comparison Between Changes in Electrocardiogram After Administration of Strophanthin, of Acetylcholine and After Irritation of Vagus. N. A. Nielsen and M. Trier.—p. 759.
- Suspension of Uterus (Alex-Adams) in Operations for Prolapse Together with Review of Complete Prolapse Material from 1924 to 1933 (1934). A. Johnson and S. Müller.—p. 768.

Changes in Electrocardiogram.—Nielsen and Trier state that the changes in the electrocardiogram after the administration of strophanthin, after the administration of acetylcholine and after irritation of the vagus in the same person are identical: bradycardia, relative shortening of the electric systole and, in case of marked bradycardia, changes in the T deflection in leads 1 and 2. This supports the assumption of acetylcholine as vagus substance and of sensitization of the heart musculature by strophanthin as due to the acetylcholine released by the normal vagus tonus.

PREVENTIVE MEDICINE

ITS OUTLOOK IN MEDICAL EDUCATION

W. S. LEATHERS, M.D.

NASHVILLE, TENN.

Our ideas concerning the prevention and control of disease have undergone remarkable transformation during the past century and especially during the past fifty years. Many of the great conquests in medicine have been achieved in the field of preventive medicine and public health. One who reads the biographies of Walter Reed, Pasteur, Trudeau or "An American Doctor's Odyssey" by Heiser is impressed with the romance and spirit of adventure which one may experience in the prevention and control of disease and in the field of medical research. The progress that has been made in this phase of medical service constitutes a record of those principles the scientific application of which should ultimately result in "man's redemption of man."

CHANGING ATTITUDES TOWARD PUBLIC HEALTH

Before the era of the science of bacteriology and immunology the practice of preventive medicine was focused on the environment. The methods employed were based largely on empiricism. Our concept of preventive medicine at that time was completely dominated by the filth theory of disease. Public health procedures, as a consequence, were directed chiefly toward the abatement of nuisances, the removal of refuse, isolation and quarantine of the sick, and disinfection. This attitude toward public health prevailed largely until the epoch-making researches of Pasteur, Koch, Lister, Loeffler, Behring, Ehrlich, Laveran, Manson and Walter Reed, whose discoveries established the etiologic and immunologic factors involved in the use of scientific methods in the diagnosis, treatment and control of the infectious diseases. The emphasis that had been placed on the environmental theory of disease during the nineteenth century began to be discarded in favor of the germ theory at the beginning of the twentieth century. There was, therefore, a change in emphasis from the environmental factors of disease to the health of the individual himself and to his relation to the family and to the community. Thus our horizon was rapidly extended to include a study of maternal, infant and preschool care, the health of the school child, the effect of physical changes of adolescence on health, and the health problems of the adult and of the family

as the most stable unit of society. Periodic medical examination and general health supervision of the community likewise became of paramount importance in the public health program.

The "trial and error" method was gradually discontinued and the newer knowledge of preventive medicine was applied in a common sense, orderly and technical way. There have been organized, as a result, during the past twenty-five years an increased number of full time county or district health departments. These are usually directed by physicians whose professional education and experience are such as to command the respect and confidence of the medical profession and of the public. Experiments prove and experiences show that the methods of preventive medicine today may be considered as dependable as those of other branches of medicine. In reality, preventive medicine constitutes a part of clinical medicine, obstetrics, pediatrics and psychiatry, and even much of surgery. Its purpose is to avert those disorders for which there are specific preventive measures; to detect early by accurate and thorough methods of diagnosis the beginnings of illness for which remedial therapy may be effectively applied. Its objective is to aid in the solution of social, economic and welfare problems of the community in relation to disease. It involves the use of a special technic in dealing with the public. The application of the principles of preventive medicine through organized administrative procedure in relation to local, state and national needs constitutes public health. Obviously, preventive medicine and public health are complementary and interdependent. Each is indispensable to community welfare.

PROGRESS IN EUROPE

The question may be asked What is the present status of preventive medicine in medical education? In 1924, through the generosity of the Rockefeller Foundation, it was possible for me to devote a year in a study of medical education and public health activities in foreign countries. These were France, England, Scotland, Switzerland, Belgium, Germany, the Netherlands, Denmark and Norway. This investigation was undertaken with particular reference to the place of preventive medicine and public health in the scheme of medical education. It was a task of trying to determine what factors must be considered to provide adequate instruction in this subject, particularly for undergraduate medical students. Much time was devoted also to a study of public health administration and the facilities afforded for the professional education of public health personnel. In 1932 it was possible for me to return to Europe as a member of the Board of Scientific Directors of the International Health Division of the Rocke-

From the Department of Preventive Medicine and Public Health, Vanderbilt University School of Medicine.
Read before the Medical Section of the Inauguration Program of President Rufus Carrollton Harris, Tulane University, New Orleans, Jan. 17, 1938.

feller Foundation. This afforded an opportunity to extend these observations in other countries, namely Spain, Italy, Yugoslavia, Bulgaria, Austria, Poland and Hungary.

Significant progress had been made in many of these countries in the development and extension of organized public health work, largely as a result of the interest and grants-in-aid of the International Health Division of the Rockefeller Foundation.

The problems of medical education were of much interest, particularly in relation to the systems of medical service which had been developed in the older countries and which have been founded more largely on principles of state control than has been done in our own country. It was possible also to study the public health organizations and the methods that were employed in the protection of individual and community health. The interchange of points of view with public health authorities and teachers in medical faculties and official groups was helpful in forming a perspective with reference to the relationships which should be maintained in medical schools between the clinical branches of the curriculum and instruction in preventive medicine, and also the relationships which should exist between public health activities and the practice of medicine.

Time will not permit a more detailed consideration of this matter. It is sufficient to state that there was obvious need for more adequate instruction of medical students in hygiene and preventive medicine in the countries visited. The instruction in this phase of medical education was chiefly of a didactic nature. The courses consisted of from ten to seventy lectures, usually in the fifth curricular year and sometimes also in the sixth. Some attention was given to laboratory exercises with particular reference to water supplies, sewage products and food adulteration. Microbiology was included in the third year curriculum in a few medical schools. The lecturers or professors were frequently members of the local health service and therefore devoted a relatively small part of their time to teaching students. The teaching facilities in preventive medicine and public health were chiefly centered in institutions of hygiene and schools of public health in which there was a predominant interest in bacteriology and immunology, including clinical aspects of the infectious diseases. But little attention was given to administrative procedures in public health in relation to the practitioner of medicine and the technical phases of personal and community hygiene. There was, however, a marked interest in providing more adequate facilities for the teaching of undergraduate medical students.

Since 1932 more consideration has been given in these countries to the instruction of undergraduate medical students. This is particularly true of Cluj, in which a course of instruction for medical students is provided along modern lines, including reasonable opportunity for laboratory exercises and field demonstrations. The course consists of "instruction in the prevention of infectious diseases, disinfection, personal hygiene, housing, nutrition, water supplies, sewage disposal, child hygiene, industrial hygiene and vital statistics. The students are required to present before examination a sanitary survey of some village." The plan of instruction for medical students is also especially noteworthy and well developed in Nancy under the able direction of Professor Parisot. The teaching staff

of the Institute of Hygiene has a full time personnel which expresses consistent interest and constructive outlook in the plan of instruction of undergraduate medical students. Progress has been made also in Hungary, Poland, Czechoslovakia and Yugoslavia in this phase of instruction. There is a forward look in countries visited with reference to providing better facilities and more adequate instruction in hygiene and preventive medicine to undergraduate medical students. The training of the physicians in hygiene and public health should not be deferred as an interest in post-graduate instruction, which unfortunately has been done largely in many countries in developing public health organizations.

SITUATION IN THE UNITED STATES AND CANADA

Early in 1925 a few months were devoted to observations in the medical schools of some of the leading universities in the United States and Canada, notably, Harvard, Yale and the University of Toronto. The situation was obviously encouraging. Provision had been made for the teaching of preventive medicine and public health to medical students. The medical school in each of these universities had a reasonably well organized department provided with a budget and full time personnel for teaching and research. In Toronto the fifth year medical students devoted three weeks to field work in public health, one half of the class taking the work at the end of the session and the other half just prior to the beginning of the session of the sixth year. In Harvard, each medical student was required to make a careful sanitary survey before graduation in medicine as a part of the regular course in hygiene and preventive medicine. At Yale provision was made for a number of field demonstrations and special studies of public health activities in the municipal and state health organization. In these medical schools a serious effort was made to give the students some knowledge of personal and community hygiene and the application of preventive measures by official health agencies and their significance in relation to medical practice.

The outlook for preventive medicine in medical education in the United States is encouraging. However, if one is to realize fully the benefits that may be derived from the available knowledge for the control of disease and the promotion of individual and community health it is necessary that authorities in medical schools give intelligent and aggressive direction in effecting more adequate arrangements and facilities for instruction of students in this phase of medical service. No plan or system is offered for realizing this objective in medical education. The solution of the problem depends obviously on an analysis of the conditions confronting the medical faculty of each university. There can be, however, no question as to the need and the advisability of affording better facilities for this type of instruction in our medical schools.

In 1926 there were nine medical schools in the United States and three in Canada that had full time departments of preventive medicine. In each of these institutions a budget was provided and full time personnel was engaged in the instruction of undergraduate medical students. Today, with the criterion of the full time department as a basis for comparison, there are now approximately eighteen full time departments in medical schools in the United States and seven in Canada. This shows an increase in our own country of 100 per cent during the past decade and in Canada of slightly more

than 100 per cent. A few of the departments that existed in 1926 have enlarged their facilities for teaching and research. Much more emphasis is being placed also on the practical aspects of instruction such as assignments for field experience, field demonstrations, epidemiologic exercises, laboratory methods for the diagnosis of communicable diseases and environmental case studies. Special studies also are being made of public health problems in the community and state health organizations; seminars are being used as a means of developing the interpretative power of the student in statistical analysis and epidemiologic observations.

INSTRUCTION

Although the didactic or lecture method should be used, within limitations, in teaching preventive medicine and public health to the medical student, practical or clinical measures must be employed to gain and maintain the interest and stimulate the imagination of the student. The plan of teaching should give the student an experience reasonably comparable to that which is afforded by the "clinical clerkship" in medicine. For example, the environmental case study is a phase of instruction which is now used in Yale, Vanderbilt, Syracuse, Johns Hopkins and possibly other universities. This directs the interest of the student especially to the individual rather than to a group of the population. A particular clinical and public health problem is undertaken in the study of the patient in relation to his family, his home, his occupation, his social-economic status and to the official and unofficial health and welfare agencies whose aid may be invoked in the solution of the treatment involved. These cases are selected cooperatively by the clinical and public health departments and the social service division of the hospital. A report is finally made by the student to the class, and representatives of the agencies concerned are invited to attend. This method of teaching affords an unusual opportunity for the student to obtain some idea of the background of disease, its significance in the economy of life and the factors that should be considered in attaining the best results in the treatment of both the patient and the disease. The students display much interest in this type of teaching. Their imagination is stimulated by a clearer understanding of the social, religious, psychologic and economic factors involved in the effective use of therapeutic and preventive measures in the control of disease.

There is need to implement the practical aspects of instruction of medical students in preventive medicine and public health. The use of procedures which will integrate this instruction with other subjects in the medical curriculum is of the greatest value. A unified purpose should be created and maintained in the faculty for teaching the principles involved in personal and community health. The student must be aroused to have the long range view in the prevention and cure of disease. This objective cannot be successfully accomplished without a full time department of preventive medicine and public health which functions not only in giving necessary formal instruction to the students but which will also relate its work to the personnel of other departments in the medical school. This serves to stimulate and maintain the interest and cooperation of members of the faculty in establishing a point of view in the medical student which will cause him later to practice preventive as well as curative medicine. In a word, unless the instruction in this field of medical

service is organized so as to carry on a well ordered, effective and dynamic teaching and research program, the interest and imagination of the undergraduate medical student will not be secured and maintained comparable to that afforded by instruction in the fundamental sciences and the clinical branches of medicine. In schools where this is accomplished, gratifying results are obtained from the point of view both of training future practitioners in the preventive aspects of medicine and of causing a larger percentage of graduates to adopt public health as a career.

Preventive medicine and public health must be integrated in the scheme of medical education so that the 5,000 graduates of medicine who are turned out annually on a receptive public will be imbued with their responsibility to use in practice available knowledge for the prevention of disease and the protection of community health, for the physician in a sense should act the part of a deputy health officer. He should have an intelligent understanding of the activities of official and unofficial health agencies in his community and state. He should cooperate in promoting the work of the local health department. He should serve as an outpost in a field of preventive medicine. He should regard himself as an integral part of the national public health program.

If this goal is achieved a great and permanent contribution will be made in providing a more adequate medical service for the indigent and the low income groups of the population. There will also be a better understanding and, as a result, a closer cooperation between public health agencies, official and unofficial, and the medical profession in the treatment and prevention of disease and, broadly speaking, in the general promotion of public health.

What motivating agencies are engaged to accomplish this result? From about 1920 the Association of American Medical Colleges and the Council on Medical Education and Hospitals of the American Medical Association have emphasized the great need for teaching preventive medicine and public health in the curriculum in the modern medical school. The records of the Association of American Medical Colleges show that provision was made in the constitution and by-laws published in 1907 in which thirty lectures were advised. However, in 1923, after a careful survey by a committee of this association, it was specified that from 3 to 4 per cent of the total number of hours (from 3,600 to 4,400) should be devoted to this type of instruction. This would mean approximately from 108 to 175 hours per year. In the *Proceedings of the Annual Congress on Medical Education and Licensure* of the American Medical Association a number of papers on this subject have been published during the past two decades concerning its place in the medical curriculum, and there appears to be an agreement between the two associations as to the minimum number of hours that should be included.

INSPECTION OF MEDICAL SCHOOLS

During a period of two years prior to May 1936, all the medical schools in the United States and Canada were inspected under the general direction of the Council on Medical Education and Hospitals of the American Medical Association. These data have been used in an attempt to evaluate the departmental activities, certain criteria being used that may be applied on a comparable basis. The Secretary of the Council on Medical Education and Hospitals in making his annual

report to the House of Delegates of the American Medical Association at its meeting in Atlantic City on June 7, 1937, made the following significant statement:
